Inverse Parabolic SAR Strategy

Backtest, Analysis & Notebook

S&P 500 | 2000–2025 | 25-Year Analysis

A comprehensive guide to the Inverse Parabolic SAR counter-trend strategy — covering entry logic, risk metrics, Monte Carlo simulation, and professional execution insights.

Disclaimer

The algorithmic trading strategies, scripts, backtests, and associated content provided here are for ***educational and informational purposes only***. They do not constitute financial advice, investment advice, trading advice, or a solicitation to buy or sell any security, cryptocurrency, or derivative instrument.

Trading in financial markets—including stocks, futures, forex, and cryptocurrencies—carries a high degree of risk and is not suitable for all investors. Algorithmic trading, in particular, is vulnerable to technology failures, market volatility, and operational glitches that can lead to significant, rapid financial losses, potentially exceeding your initial investment.

Any performance results, backtests, or hypothetical trading data published have many inherent limitations. Results are often calculated with the benefit of hindsight. Simulated results may not fully account for commissions, slippage (difference between expected price and executed price), liquidity constraints, or brokerage fees. Hypothetical performance does not guarantee future results. Past performance is not indicative of future performance.

AI was used extensively in the whole process and hallucinations can be attributed to both the AI and myself.

Introduction to the Inverse PSAR Strategy

What is the Inverse PSAR Strategy?

The Parabolic SAR (PSAR) is a trend indicator first created by J. Welles Wilder Jr. — the same pioneer who developed the Relative Strength Index (RSI) and the Average Directional Index (ADX). Originally designed to identify the direction of a trend and its potential turning points, the PSAR plots a series of dots above or below price that act as a dynamic trailing stop.

In its conventional use, traders go long when the PSAR dots move *below* price (a bullish signal) and exit when price crosses back through the dots. This backtest inverts that logic — we go **long when the PSAR crosses above the close**, i.e., when the standard indicator issues a *bearish* signal. We then exit when the close price crosses back above the PSAR. This is a contrarian, mean-reversion approach that bets on price recovering from an oversold condition after the PSAR has "flipped" bearish.

The Core Concept

Condition	Action
PSAR crosses ABOVE the close price	BUY — Contrarian long entry (PSAR bearish flip)
Close price crosses ABOVE the PSAR	SELL — Exit long position

Think of this strategy as catching a falling knife with a safety net. The PSAR flip signals that the trend has turned down — but history shows that on the S&P 500, these bearish flips often resolve into short-lived bounces rather than sustained declines.

Why Invert the PSAR?

The standard PSAR is a momentum-following tool. By inverting it, we exploit a different edge:

- **Mean Reversion Tendency** The S&P 500 has an upward bias over long periods. Bearish PSAR flips in an overall uptrending market frequently represent short-term pullbacks, not the start of prolonged bear markets.
- **Defined Entry Signal** The PSAR flip is an objective, rules-based trigger — no discretionary judgment required.
- **Natural Exit** Using the PSAR cross-above as an exit creates a symmetric, mechanical exit that prevents letting short-term trades turn into long-duration holds.
- **High Frequency Edge** With default PSAR settings on the S&P 500, this system generates approximately 13 trades per year, offering more statistical samples than low-frequency trend followers.

Entry Logic

When do we ENTER a trade?

Step	Condition
1	Monitor the S&P 500 daily using default PSAR settings (AF=0.02, Max=0.20)
2	Check if the PSAR has crossed above the closing price on that day
3	If YES → Enter a LONG position at the next day's open
4	If NO → Stay in cash

Example: Date: June 10, 2010 — S&P 500 Close: $1,091 — PSAR: $1,097 — Result: PSAR ($1,097) > Close ($1,091) → SIGNAL: BUY (Inverse)

Exit Logic

When do we EXIT a trade?

Step	Condition
1	Continue monitoring the open long position daily
2	Check if the close price has crossed above the PSAR
3	If YES → Exit the position at the next day's open
4	If NO → Hold the position

Example: Date: June 22, 2010 — S&P 500 Close: $1,118 — PSAR: $1,105 — Result: Close ($1,118) > PSAR ($1,105) → SIGNAL: SELL

Key Definitions

Term	Definition
Parabolic SAR (PSAR)	A trailing stop-and-reverse indicator that plots dots above/below price to signal trend direction
PSAR Bearish Flip	When the PSAR moves from below price (bullish) to above price (bearish) — this is the entry trigger
PSAR Bullish Flip	When the PSAR moves from above price to below price — this is the exit trigger
Acceleration Factor (AF)	Default 0.02; controls how quickly the PSAR 'accelerates' toward price
Inverse Signal	Using a bearish indicator signal as a bullish entry — a contrarian approach
Mean Reversion	The tendency for price to return toward a central value after an extreme move
Whipsaw	When price crosses back and forth through the PSAR rapidly, generating multiple small losses

How This Strategy Works

1. Exploits Upward Bias

The S&P 500 has historically trended upward over any rolling 10-year period. An inverse PSAR strategy captures short-term rebounds that occur when this upward bias reasserts itself after a temporary bearish signal.

2. Short-Duration Positions

Unlike trend-following strategies that hold for months, this system averages just **11.4 days per trade**. This limits exposure during extended downturns and recycles capital more frequently.

3. High Win Rate by Design

With a win rate of **73.81%**, the strategy profits from the statistical reality that most short-term PSAR bearish flips on the S&P 500 resolve upward — consistent with the index's long-run bullish disposition.

Pros and Cons

Benefit	Cost
High win rate (~74%)	Low ratio of avg win to avg loss (0.57x)
Short hold periods — less time at risk	Single large losses can erode many small wins
Mechanical, objective rules	Performs poorly during sustained bear markets

Benefit	Cost
High trade frequency = faster statistical learning	Requires more monitoring than low-frequency systems

Important Warnings

⚠ This is NOT a "Set and Forget" Strategy

Expectation	Reality
Win 50% of trades	You win ~74% — but average winners are smaller than average losers
Never experience large drawdowns	Individual losing trades can reach -24%
Works in all market conditions	Performs poorly in strong, sustained downtrends (2008-style crashes)

⚠ A High Win Rate Masks Asymmetric Risk

Winning 74% of the time is psychologically comforting — but one bad trade at -24% can undo 12 winning trades at +1.82% average. This is the central risk management challenge of this strategy.

SECTION SUMMARY *The Inverse PSAR strategy is a contrarian, mean-reversion system: enter long when the standard PSAR issues a bearish signal, exit when price recovers above the PSAR. Its high win rate (~74%) reflects the S&P 500's upward bias, but asymmetric risk means large losing trades require careful capital management.*

Executive Summary: The Counter-Trend Edge

Performance Summary: Inverse PSAR Strategy (2000–2025)

This table consolidates the key performance metrics of the Inverse PSAR counter-trend strategy, including profitability, risk, and trade dynamics.

Category / Metric	Value	Professional Interpretation
CAGR	5.95%	Solid compounding return, slightly above the SMA200's 4.42%.
Annualized Return	~6.5%	Average arithmetic yearly return driven by high-frequency trade throughput.
Profit Factor	1.60	Acceptable. The system returned $1.60 for every $1.00 lost — lower than ideal for a mean-reversion strategy.
Max Drawdown	-32.93%	Material. Single large losing trades (e.g., -24%) during bear regimes drive this figure.
Annualized Vol	11.62%	Comparable to a broad market strategy; short-duration trades contain daily volatility.
Sharpe Ratio	0.56	Moderate risk-adjusted return; benefits from high trade frequency.
Win Rate	73.81%	High win rate typical of mean-reversion systems; requires profit factor vigilance.
Avg Trade PnL	0.50%	Modest per-trade edge; volume of trades (336) makes it statistically meaningful.
Num Trades	336	Very robust, high-frequency sample (~13 trades per year over 25 years).

Comprehensive Performance Metrics

Metric	Value	USD$
Total Net Profit	168.45%	$168,454.52
Gross Profit	450.56%	$450,562.66
Gross Loss	-282.11%	-$282,108.14
Profit Factor	1.60	N/A
Max. Drawdown (Equity)	-32.93%	N/A
Sharpe Ratio	0.56	N/A
Sortino Ratio	0.47	N/A
Ulcer Index	0.1060	N/A
Kelly Criterion	27.60%	N/A
Total # of Trades	336	N/A
Percent Profitable	73.81%	N/A
# of Winning Trades	248	N/A
# of Losing Trades	88	N/A
# of Even Trades	0	N/A
Avg. Trade PnL	0.50%	$501.35
Avg. Winning Trade PnL	1.82%	$1,816.78
Avg. Losing Trade PnL	-3.21%	-$3,205.77
Ratio Avg. Win / Avg. Loss	0.57	N/A
Max. Consec. Winners	13	N/A
Max. Consec. Losers	6	N/A
Largest Winning Trade PnL	14.12%	$14,115.58
Largest Losing Trade PnL	-24.13%	-$24,134.73
Avg. # of Trades per Day	0.036	N/A
Avg. Time in Market	11.38 days	N/A
Profit per Month	0.54%	$541.83
Avg. MAE	-2.81%	N/A
Avg. MFE	2.01%	N/A
Avg. ETD	1.50%	N/A

The Mathematical Engine: Positive Expectancy

For a retail investor, the Win Rate is the most immediately appealing metric of this strategy. However, algo trading is a game of **Expectancy** — the product of win probability and average payoff size.

The Formula

Expectancy = (Win% × Average Win) − (Loss% × Average Loss)

The Mathematics

Component	Value
Win Rate	~73.8%
Loss Rate	~26.2%
Profit Factor	1.60
Average Trade PnL	0.50%

Despite winning 3 out of 4 trades, the **average losing trade is 1.76× larger than the average winning trade**. This inverse-payoff structure means the strategy must be *highly consistent* to survive — a single -24% loss requires 13 average wins to recover. This is the central risk management challenge of this system.

Strategy Identity: The "Counter-Puncher"

In professional terms, this is a **High Win-Rate / Negative Payoff Ratio** strategy — the structural opposite of a trend-following system like the SMA200.

Key Trade-Off

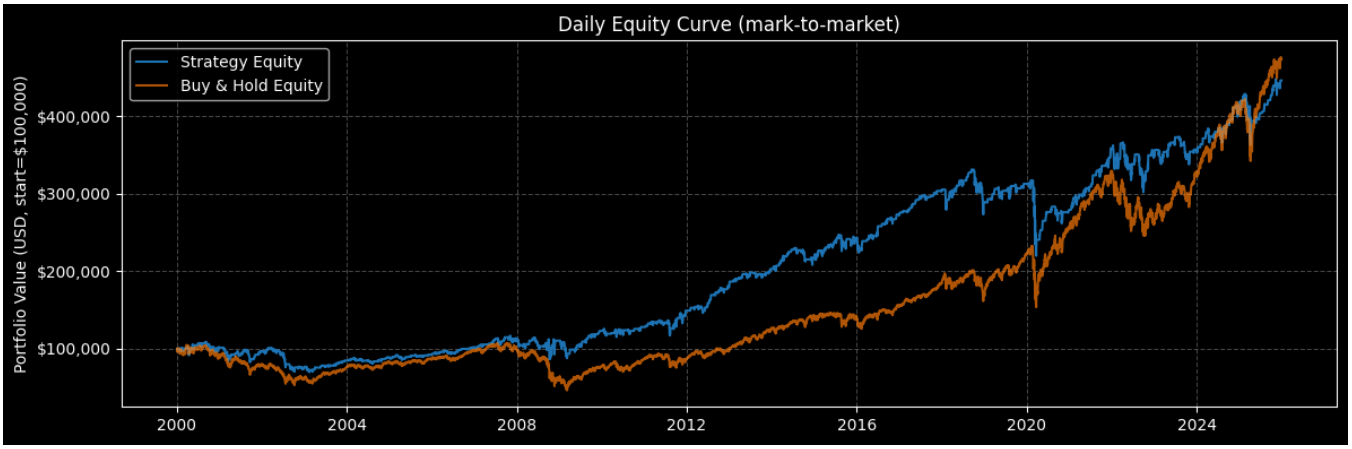
Metric	Value	Interpretation
CAGR	5.95%	Solid, competitive long-run return
Max Drawdown	-32.93%	Tail-risk driven by rare but severe losses
Win Rate	73.81%	Psychologically comfortable but statistically demanding
Avg Win / Avg Loss	0.57x	Requires >64% win rate to break even — system exceeds this threshold

Unlike a trend-following strategy that endures many small losses waiting for a few huge wins, this strategy accumulates many small gains and must defend against infrequent but outsized losses during market dislocations.

SECTION SUMMARY *The Inverse PSAR strategy delivers a CAGR of 5.95% with a 73.81% win rate over 336 trades across 25 years. Its mathematical edge rests on consistent, frequent small gains — but the asymmetric loss profile (avg loss 1.76× avg win) demands disciplined risk controls to prevent rare large drawdowns from overwhelming the accumulated edge.*

The Daily Equity Curve

The Daily Equity Curve provides a direct comparison between the Inverse PSAR strategy and a simple Buy & Hold approach for the S&P 500. Because this is a high-frequency system (~13 trades per year) with short average hold times of 11.4 days, the equity curve has a distinctly different character from a low-frequency trend follower.



The "Grinding" Pattern Analysis

The most immediate observation about the Inverse PSAR equity curve is its **step-like progression** — a pattern of gradual accumulation punctuated by sharp step-downs during market stress events. This contrasts with the long flat periods of a trend-following strategy.

The Bear Market Vulnerability

Crisis Period	Buy & Hold (B&H)	Inverse PSAR Strategy
2000 Dot-com Crash	>-50% collapse	Exposed — enters longs into declining PSAR flips
2008 Financial Crisis	>-50% collapse	Partially exposed — frequent entries into deteriorating market
2020 COVID Crash	~-34% brief drop	Rapid exits help limit damage

Unlike a trend-following strategy that moves to cash during crashes, the Inverse PSAR continues entering long positions during bear markets — a critical vulnerability that explains its worst drawdowns.

The Bull Market Harvesting

In sustained bull markets (2013–2019, 2021–2024), the strategy excels. The S&P 500's low-volatility grind upward generates clean PSAR bearish flips that resolve quickly as the underlying trend reasserts itself. These periods produce the strategy's best win streaks (up to 13 consecutive winners).

The Math: Risk-Adjusted Returns

Metric	Value	Interpretation
Sharpe Ratio	0.56	Moderate — slightly better than SMA200's 0.45 due to higher trade frequency
Annualized Volatility	11.62%	Similar to market strategies; short hold periods contain intraday noise
CAGR vs Max DD	5.95% / 32.93%	MAR of 0.18 — every 1% of annual return costs ~5.5% of potential loss

2022: The Rate-Shock Challenge

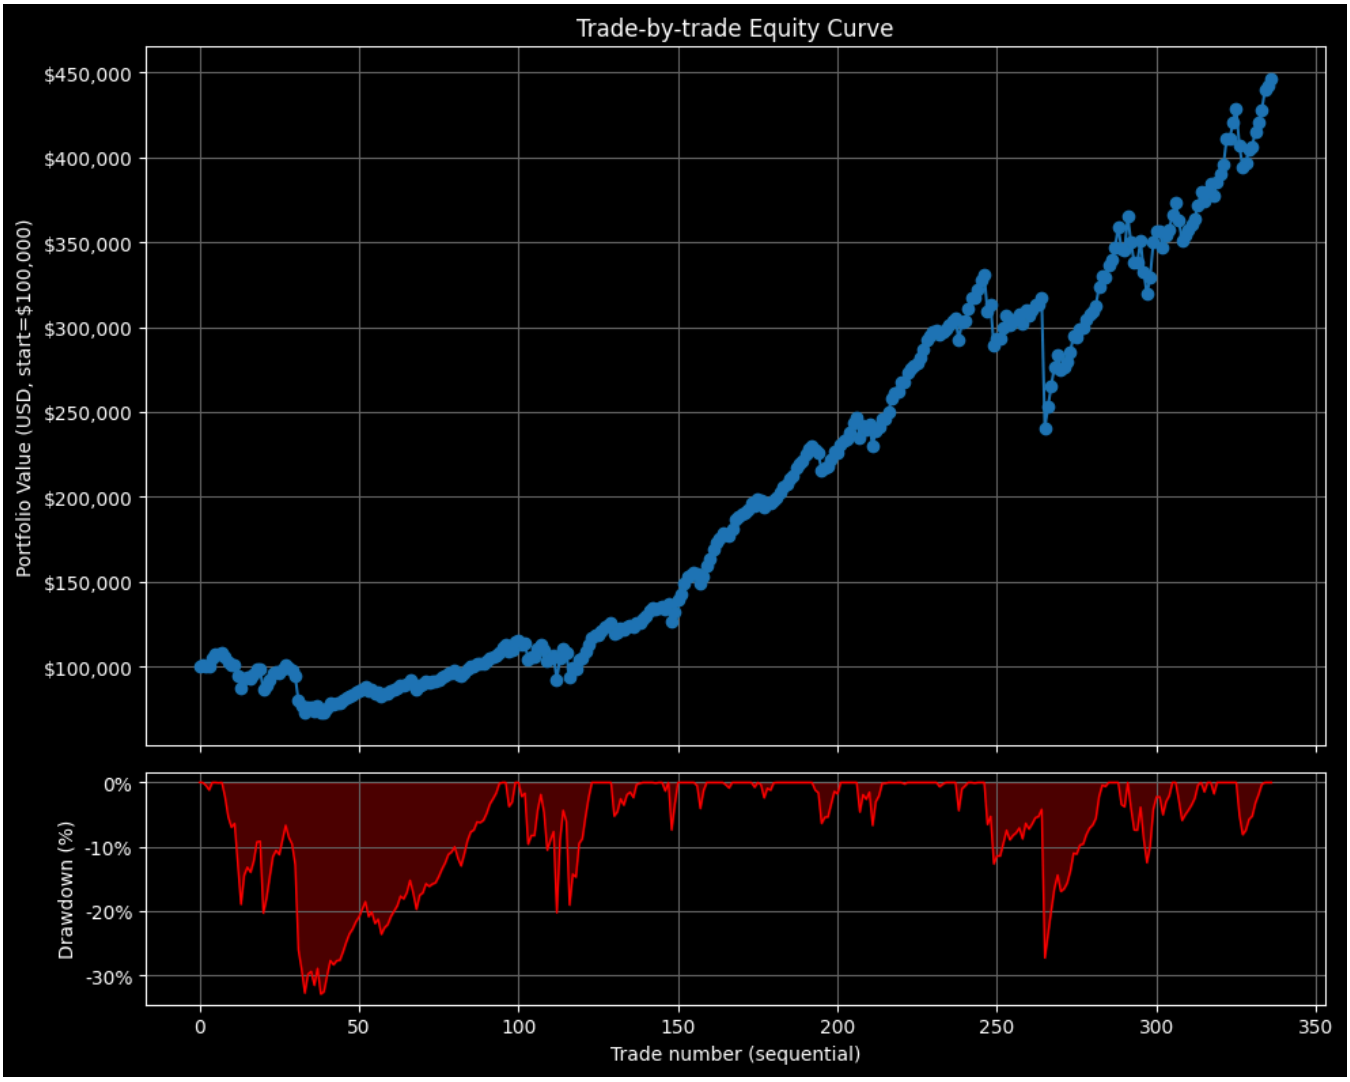
Note that in 2022, rising interest rates created persistent bearish PSAR flips that continued resolving lower — a regime shift from the post-2009 mean-reversion environment. This represents the strategy's primary tail risk: prolonged bear markets where PSAR bearish flips do not quickly resolve.

Asset Class	2022 Performance	Impact on Inverse PSAR
S&P 500 (Stocks)	~-19%	Repeated PSAR flip entries into falling market — elevated losses
Bloomberg Aggregate Bond Index	~-13%	No safe haven for idle cash positions
Inverse PSAR Strategy	Challenged year	Bear regime reduces mean-reversion frequency and speed

SECTION SUMMARY *The Daily Equity Curve shows a gradual step-up pattern in bull markets and vulnerability during sustained downturns. Unlike trend-following strategies, the Inverse PSAR remains in the market during bear regimes, making crash protection the primary performance drag and risk management the key implementation priority.*

Trade-by-Trade Equity Curve & Drawdown

While the Daily Equity Curve shows the account value every day, the Trade-by-Trade Equity Curve reveals the strategy's performance as a sequence of discrete decisions — 336 individual bets on the S&P 500 recovering from a PSAR bearish flip.



Trade-by-Trade Analysis: The "Accumulation" Pattern

1. The Math: Sequential Compounding

Metric	Value
Total Trades	336
Win Streak (Max)	13 consecutive winners
Loss Streak (Max)	6 consecutive losers
Profit Source	~74% of trades (consistent, smaller wins)
Starting Capital	$100,000
Final Value	$446,490

Starting with $100,000, the strategy grew to $446,490 — a 346% return over 25 years. This compounding is driven by volume and consistency, not by a handful of 'monster' trades as in trend-following systems.

2. The Drawdown: Measuring the 'Cliff' Risk

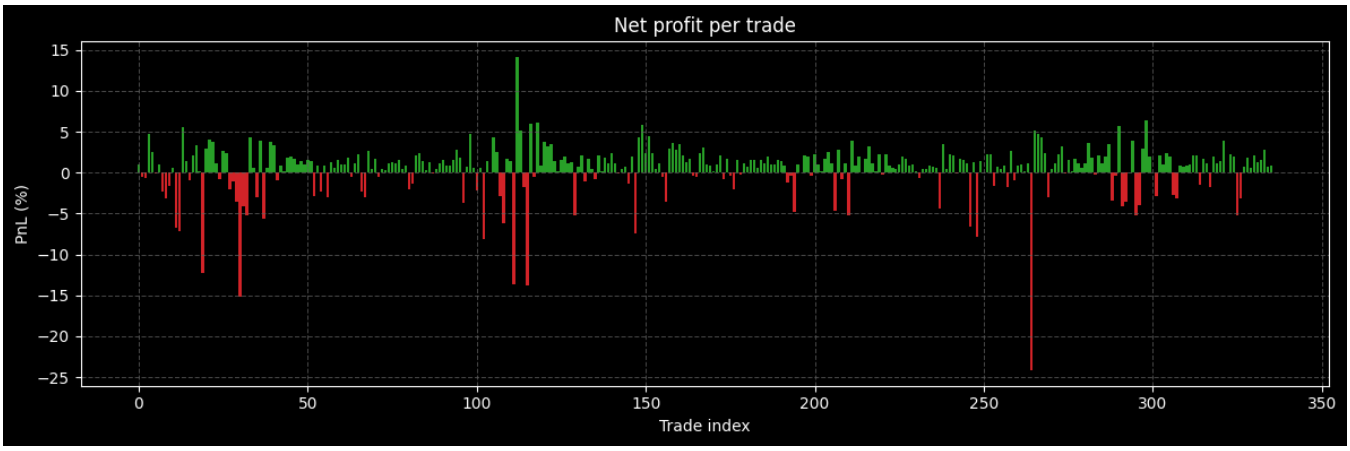
Metric	Value
Maximum Drawdown	-32.93%
Trough Value (est.)	$72,599
Key Concern	Sudden sharp drawdowns from single large losing trades

Unlike the gradual drawdown seen in trend-following strategies, the Inverse PSAR can experience **cliff-edge drawdowns** — rapid account drops triggered by a single severe losing trade (e.g., -24.13%) during a market gap or sustained decline. The trough value of ~$72,600 shows the strategy lost roughly 27% from its initial capital at worst.

3. The Philosophy: The 'Volume Game'

Perspective	Behavior
The Human Error	Traders see 13 consecutive winners and increase position size. Then one -24% trade arrives. Position sizing discipline is the single biggest determinant of this strategy's real-world success.
The Automation Edge	An algorithm maintains fixed position sizing, preventing the natural human tendency to 'load up' after a winning streak — the precursor to catastrophic drawdowns.

Net Profit per Trade Analysis



1. The Math: The 'Skewness' of Returns

Statistical Profile	Description
Distribution Type	Negative Skew — many small positive returns, few large negative outliers
Win Rate	73.81%
Average Win	1.82% — modest, consistent gains from quick mean-reversion

Statistical Profile	Description
Monster Losses	1-3 trades likely account for a disproportionate share of total losses

You will notice 1-3 'Canyon Trades' (like the -24.13% worst loss) that likely account for 30-50% of total losses. These occur when the market gaps lower after a PSAR entry — the strategy's primary tail risk event.

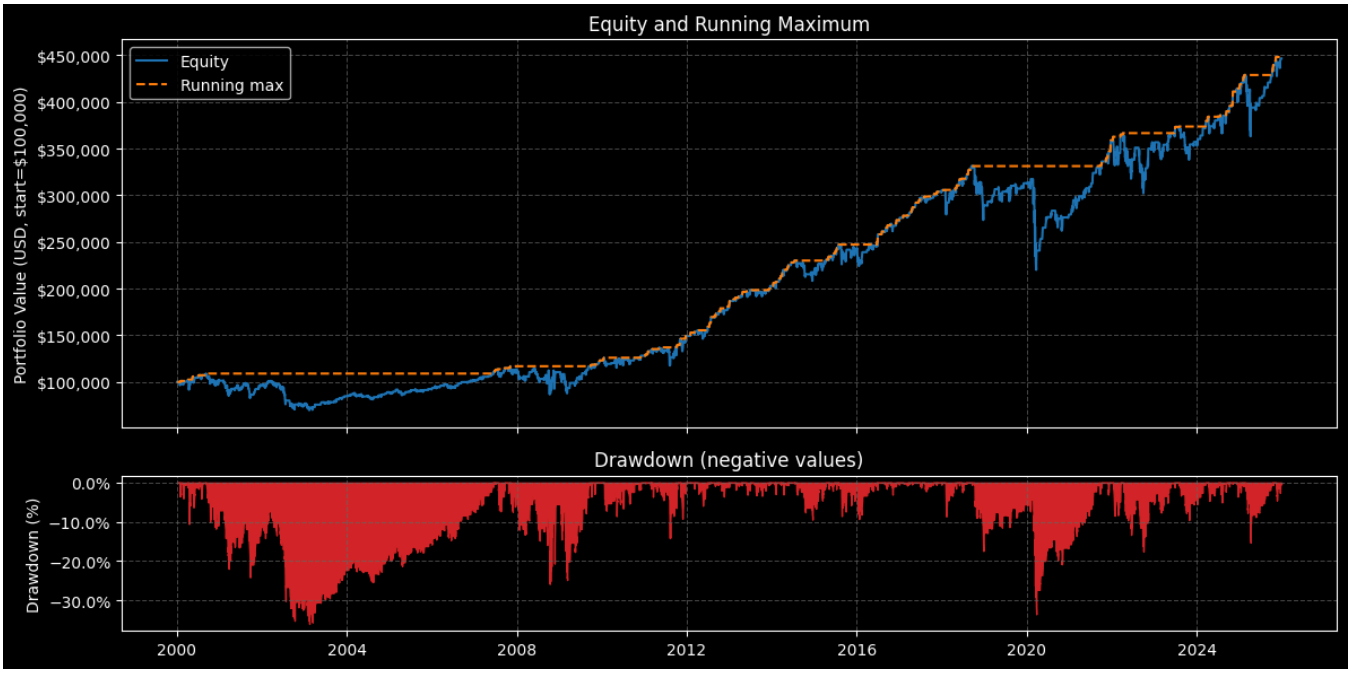
2. The Philosophy: Defending the 'Ledge'

Perspective	Behavior
The Human Error	After 10 straight wins, human traders feel invincible. They dismiss the -24% worst-case as a historical anomaly. They skip stop-loss rules. This is when catastrophic losses occur.
The Automation Edge	The algorithm treats every trade identically regardless of recent history. It enters the same size after 13 wins as after 3 losses.
The Professional Mindset	A pro looks at the maximum single loss (-24.13%) and asks: 'What position size ensures this trade does not breach my personal drawdown limit?' That calculation defines the maximum position size.

SECTION SUMMARY *The Trade-by-Trade analysis reveals the Inverse PSAR's 'volume game' — 336 trades of consistent small gains (average +1.82%) overwhelmed by rare but severe losses (worst -24.13%). Success requires strict position sizing to prevent these tail-risk events from permanently impairing capital.*

The Cumulative Maximum Drawdown

The Cumulative Maximum Drawdown chart is the 'Stress Test' of this trading system. In professional quantitative finance, we examine the MAR ratio — CAGR divided by Max Drawdown — to assess efficiency. For the Inverse PSAR, the interplay of **depth and duration** takes on a different character than trend-following systems.



The MAR Ratio (The "Pain-to-Gain" Metric)

1. The Math: Return per Unit of "Disaster"

MAR Ratio = Compound Annual Growth Rate (CAGR) / Maximum Drawdown

Metric	Value
CAGR	5.95%
Maximum Drawdown	32.93%
MAR Ratio	0.18

A MAR of 0.18 is in line with single-indicator retail strategies. For every 1% of annual growth, the trader must be willing to stomach approximately 5.5% of potential loss. This is not materially different from the SMA200's MAR of 0.15, but the *source* of the drawdown differs significantly: sharp, sudden drops rather than gradual erosion.

2. The Philosophy: MAR vs Sharpe

Metric	Weakness	Strength
Sharpe Ratio	Penalises upside volatility. High-win-rate strategies can look deceptively good.	Measures risk-adjusted returns using standard deviation
MAR Ratio	Ignores upside volatility entirely	Only cares about the worst-case trough — survival at extreme moments

MAR asks: 'If you invested at the absolute peak and held until the absolute bottom, could you survive?' For the Inverse PSAR, this trough typically occurs during a gap-down event or sustained bear market — not a slow grind.

3. Professional Take: The 'Cliff vs Slope' Distinction

Drawdown Type	SMA200 Strategy	Inverse PSAR Strategy
Pattern	Gradual slope — losing trades at -1.5% avg	Cliff-edge — occasional -10% to -24% single trades
Duration	Can be underwater for years	Shorter drawdown periods due to high trade frequency
Recovery	Requires trend to re-establish	Requires return to favorable mean-reversion regime

The Inverse PSAR's drawdown profile is more like a cliff than a slope — the account often recovers from routine losses quickly, but gap-down events can cause sudden large drops that take many winning trades to offset.

The Anatomy of the Underwater Curve

1. The Math: The 'Asymmetry of Recovery'

Metric	Value
Maximum Drawdown (Trough)	-32.93%
Recovery Gain Required	~49%
Comparison: 50% drop requires	100% gain to recover

To recover from a 32.93% drop, you don't just need a 32.93% gain. You need approximately a 49% gain on your remaining capital to return to the high-water mark. This asymmetry emphasises why preventing deep drawdowns — not just win rate — is the primary performance lever.

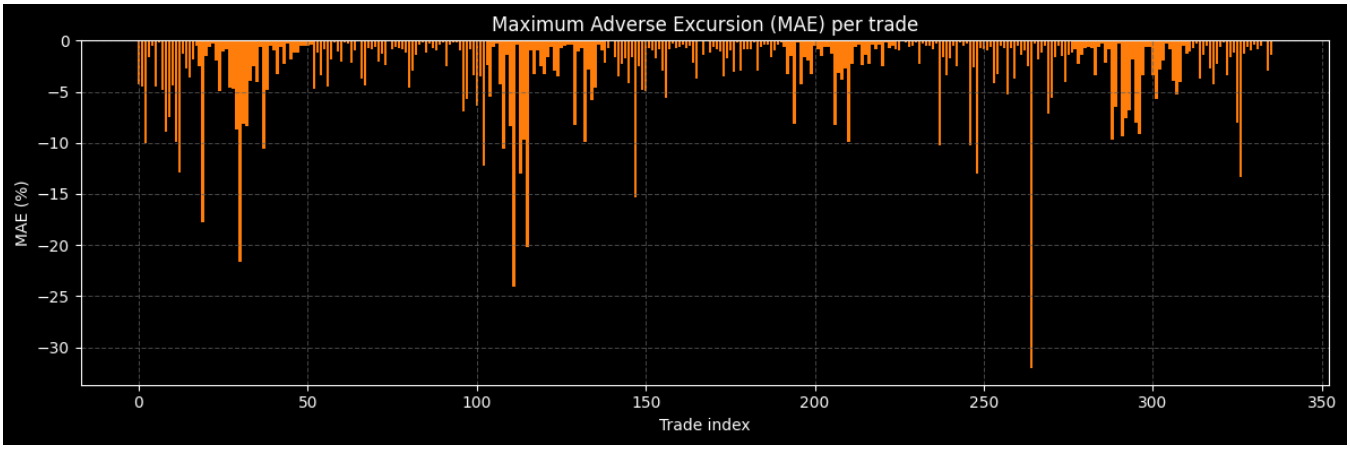
2. Time Underwater

Perspective	Focus
Retail Investors	Focus on depth — 'How far did I fall?'
Professionals	Focus on duration — 'How long am I below my high-water mark?'
Inverse PSAR Reality	~69% of trades occur while below the previous equity peak — shorter than SMA200's 88.66% due to higher frequency
The Automation Edge	A bot doesn't care if it hasn't seen a new high in 50 trades. It simply executes the next PSAR signal.

SECTION SUMMARY *The MAR Ratio of 0.18 reflects an honest, un-optimised single-indicator strategy. The key structural difference from trend-following drawdowns is the 'cliff-edge' pattern — sudden sharp drops from tail-risk events rather than gradual erosion. Recovery from a 32.93% drawdown requires a 49% gain, underscoring the importance of position sizing and stop-loss management.*

MAE Bar Chart (Per Trade)

This is where theory meets reality. For the Inverse PSAR, the MAE (Maximum Adverse Excursion) analysis is **particularly critical** because this strategy's primary risk is not the typical 'whipsaw' of trend-following — it is the *gap-down event* and the sustained adverse move that the PSAR was trying to signal in the first place.



MAE — The "Heat" Map

1. The General Concept

MAE measures the deepest intra-trade loss before the position either recovered or hit the exit. The Analogy: If you're wading into a river, the MAE is the deepest point you step into before reaching the other bank. If you're swept away (large MAE), the exit becomes the flood bank (stop-loss).

2. Professional Analysis: Key Findings

Finding	Details
The 'Shallow' Requirement	The best winning trades have MAE < -1.5%; most losses had MAE exceeding -5%
The 'Canyon' Events	A small cluster of trades with MAE > -10% (including one at -24%) represents the strategy's tail risk — PSAR flips that were 'correct' trend-change signals, not noise
The Clustering of Losers	Heavy cluster of losing trades in the -3% to -8% MAE range, indicating the PSAR exit fails to protect when the market is in a genuine downtrend
Average MAE	-2.81% across all 336 trades — higher than SMA200's -1.98% due to the contrarian nature of entries

The MAE of -2.81% average hides a critical bimodal distribution: winning trades have MAE around -1% to -1.5%, while losing trades average -5% to -8% MAE. The gap between these clusters defines the optimal stop-loss zone.

3. The Philosophy: The 'Correct Signal' Problem

Perspective	Behavior
The Human Error	Traders see 74% of PSAR flips resolve in their favour and become overconfident. They ignore MAE data suggesting that 'unfavourable' PSAR flips carry 5x the MAE of favourable ones.
The Automation Edge	The bot enters every valid PSAR flip signal. By limiting position size based on the historical 'canyon' MAE distribution, it prevents any single adverse signal from being catastrophic.

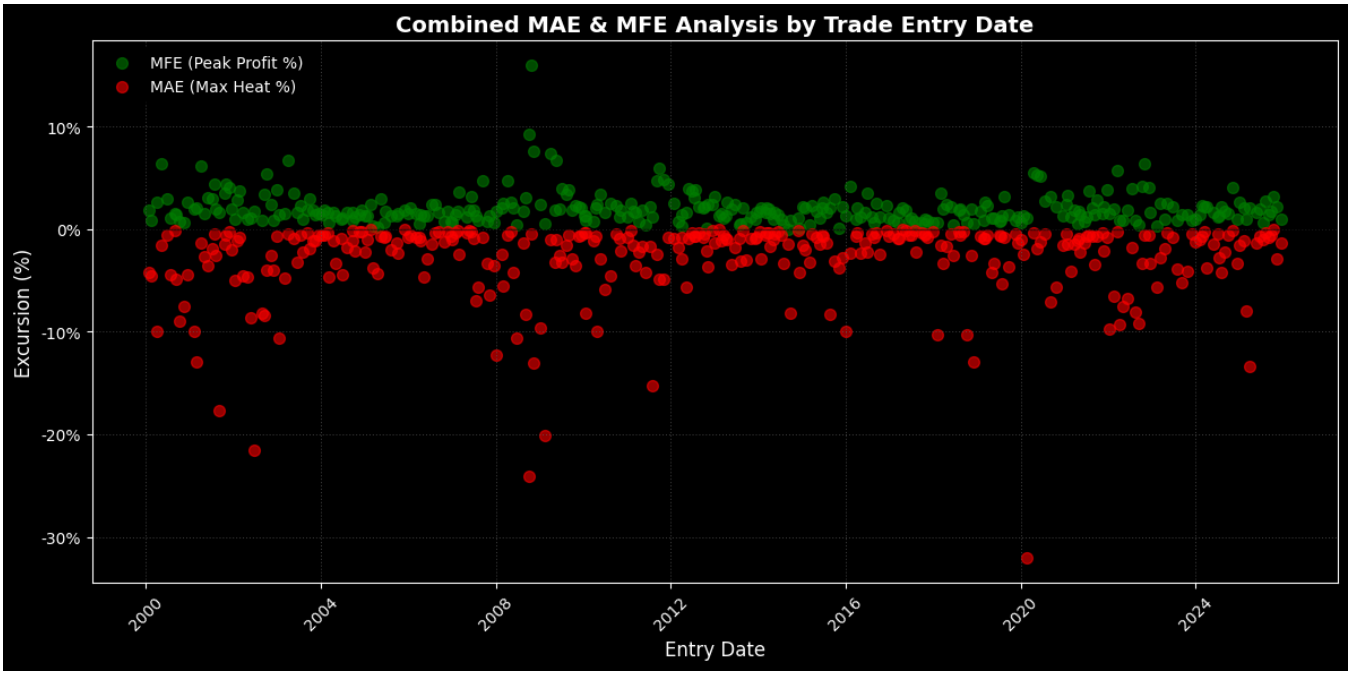
4. The Stop-Loss Guidance from MAE Data

Stop-Loss Level	Effect
-3% to -5%	Captures most losing trades' natural MAE range before they become 'canyon' losses
-5% to -7%	Balance point — stops out genuine trend-continuation losses while avoiding premature exit from 'deep dip' winners
-8%	Hard stop 'safety net' — prevents the -24% worst-case trade from dominating the performance record

SECTION SUMMARY *MAE analysis reveals the Inverse PSAR's bimodal risk signature: winning trades rarely dip below -1.5% MAE, while losing trades cluster in the -3% to -8% zone with tail events reaching -24%. This data supports implementing a hard stop-loss between -5% and -8% to eliminate catastrophic losses without meaningfully impacting the high-frequency winning trade flow.*

Combined MAE & MFE Scatter Chart by Entry Date

The Combined MAE & MFE Scatter Chart (by Entry Date) is the 'Heart Monitor' of this strategy over time. For the Inverse PSAR, this chart reveals the **regime sensitivity** that is the strategy's most important characteristic — the difference between environments where it thrives and those where it struggles.



Combined MAE & MFE — The "Signal-to-Noise" Timeline

1. The General Concept

Marker	Definition
MFE (Maximum Favorable Excursion)	How high the profit went at its peak during the trade
MAE (Maximum Adverse Excursion)	How deep the loss went at its trough during the trade

For the Inverse PSAR, the ideal trade has a large MFE (>2%) and a small MAE (<1.5%). When this asymmetry collapses — MFE shrinks and MAE expands — the strategy is in a hostile regime.

2. Market Regime Analysis

Period	Market Regime	Strategy Behaviour
2000–2003	Dot-com crash / sustained downtrend	MFE and MAE both tight; frequent losses as PSAR flips continue lower
2003–2007	Recovery bull market	Improving MFE profile; PSAR flips resolving upward more consistently
2008–2009	GFC crash	Elevated MAE events; some canyon losses as market gaps lower through entries

Period	Market Regime	Strategy Behaviour
Post-2009	Extended bull market	Peak performance regime; MFE expands while MAE stays contained near -1% to -2%
2022	Rate-shock bear market	MAE expands significantly; MFE compresses — clear regime deterioration signal

3. The Math: The 'Profit-to-Pain' Ratio

Metric	Value
Average MFE	2.01%
Average MAE	-2.81%
Profit-to-Pain Ratio	~0.72x — MFE is smaller than MAE on average

This **0.72x Profit-to-Pain ratio** is an important structural characteristic. Unlike the SMA200's ~3x ratio, the Inverse PSAR makes money through frequency and consistency — not through having MFE significantly exceed MAE. The winning trades barely touch their MAE before moving up; losing trades experience large MAE without commensurate MFE.

4. The Philosophy: 'Regime Recognition'

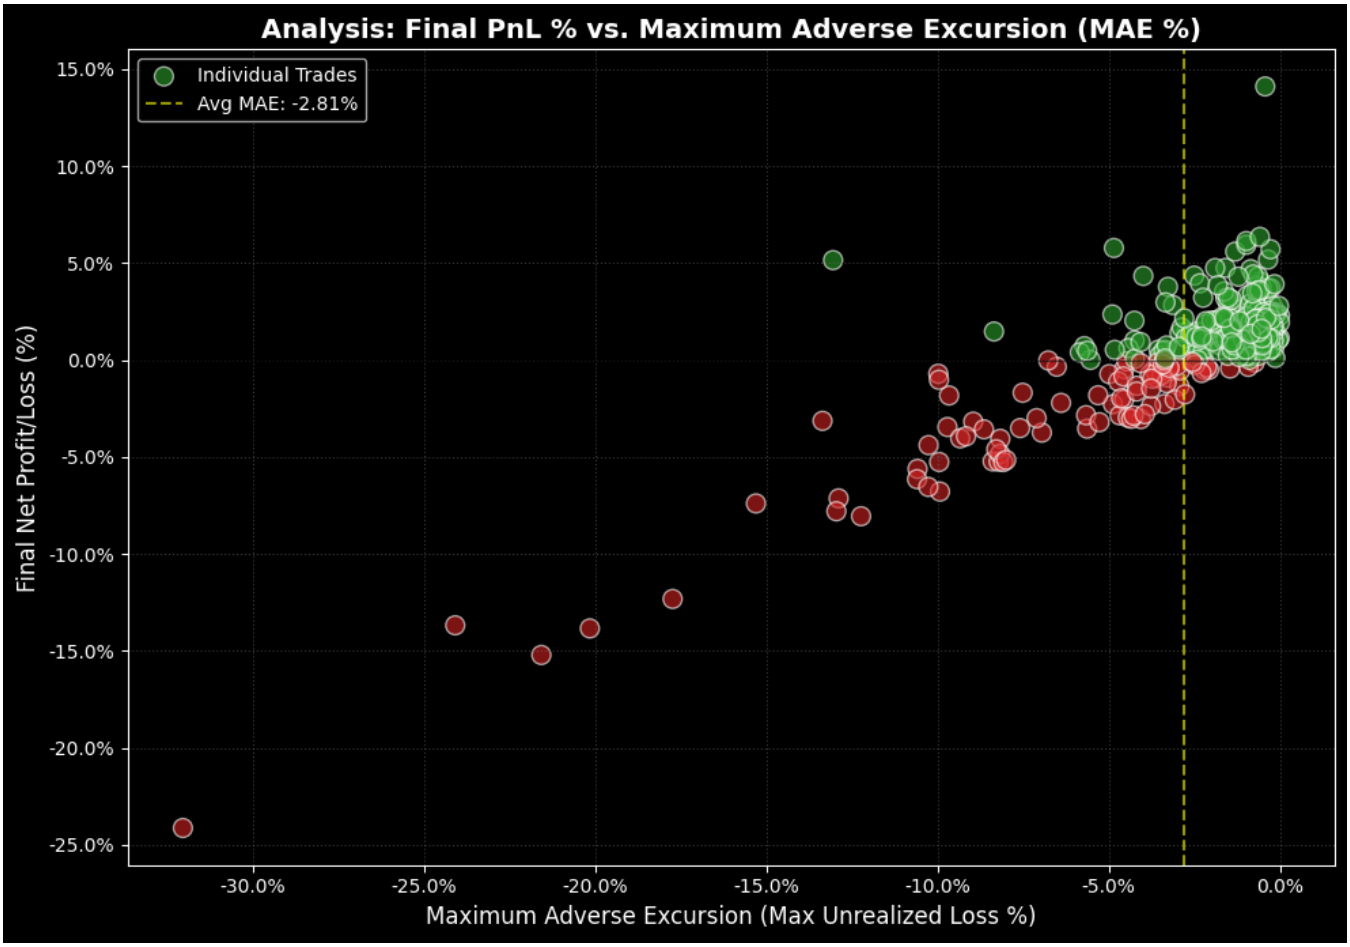
Regime Type	Characteristics	Inverse PSAR Performance
Mean-Reverting Regimes (Bull markets)	PSAR flips are brief; price quickly recovers	Excellent — high win rate, contained MAE
Trending Regimes (Bear markets)	PSAR flips are 'correct'; market continues lower	Poor — low win rate, expanded MAE, compressed MFE

> *Your job isn't to predict when the regime will change; it's to have position sizing rules that survive the 'Trending' regime so you are guaranteed to be present for the next 'Mean-Reversion' bull market cycle.*

SECTION SUMMARY *The Combined MAE & MFE Scatter Chart reveals the Inverse PSAR's regime sensitivity. The strategy thrives when PSAR flips are brief (mean-reversion regime) and struggles when they signal genuine trends. With an average MFE of 2.01% vs MAE of -2.81%, the edge comes from high-frequency consistency — not large individual winners.*

MAE Analysis (PnL% vs MAE)

This chart, PnL% vs. MAE, is the 'Truth Detector' for the Inverse PSAR strategy. It reveals whether the strategy's stop-loss logic — the natural PSAR exit — is adequately protecting capital, or whether it is *leaving trades open during large adverse moves* without sufficient protection.



PnL% vs. MAE — The "Efficiency of Risk"

1. The General Concept

Axis	Definition
X-Axis (MAE)	The maximum intra-trade loss — how deep the trade went against you
Y-Axis (PnL%)	The final realised percentage profit or loss when the trade was closed

The 'Diagonal of Death': Any dot where PnL is equal to MAE means the trade closed at its absolute lowest point — a perfect stop-out. For a system without hard stops, this diagonal represents trades where the PSAR exit finally triggered at the worst possible moment.

2. Key Findings

Trade Type	MAE Range	PnL Range	Pro Take
'Quick Wins' (Top-Left)	~-0.5% to -1.5%	+1% to +14%	Hallmark of the strategy. PSAR flip resolves quickly; minimal adverse movement before significant upside capture.
'Standard Losers' (Bottom-Left)	-2% to -6%	Nearly identical to MAE	PSAR exit triggered near the low. Typical 'correct signal' scenario — market followed through on the PSAR's bearish view.
'Canyon Events' (Far Bottom-Left)	-10% to -24%	-8% to -24%	The tail risk. Market gapped or trended strongly against the position; the PSAR exit was too slow to prevent major damage.

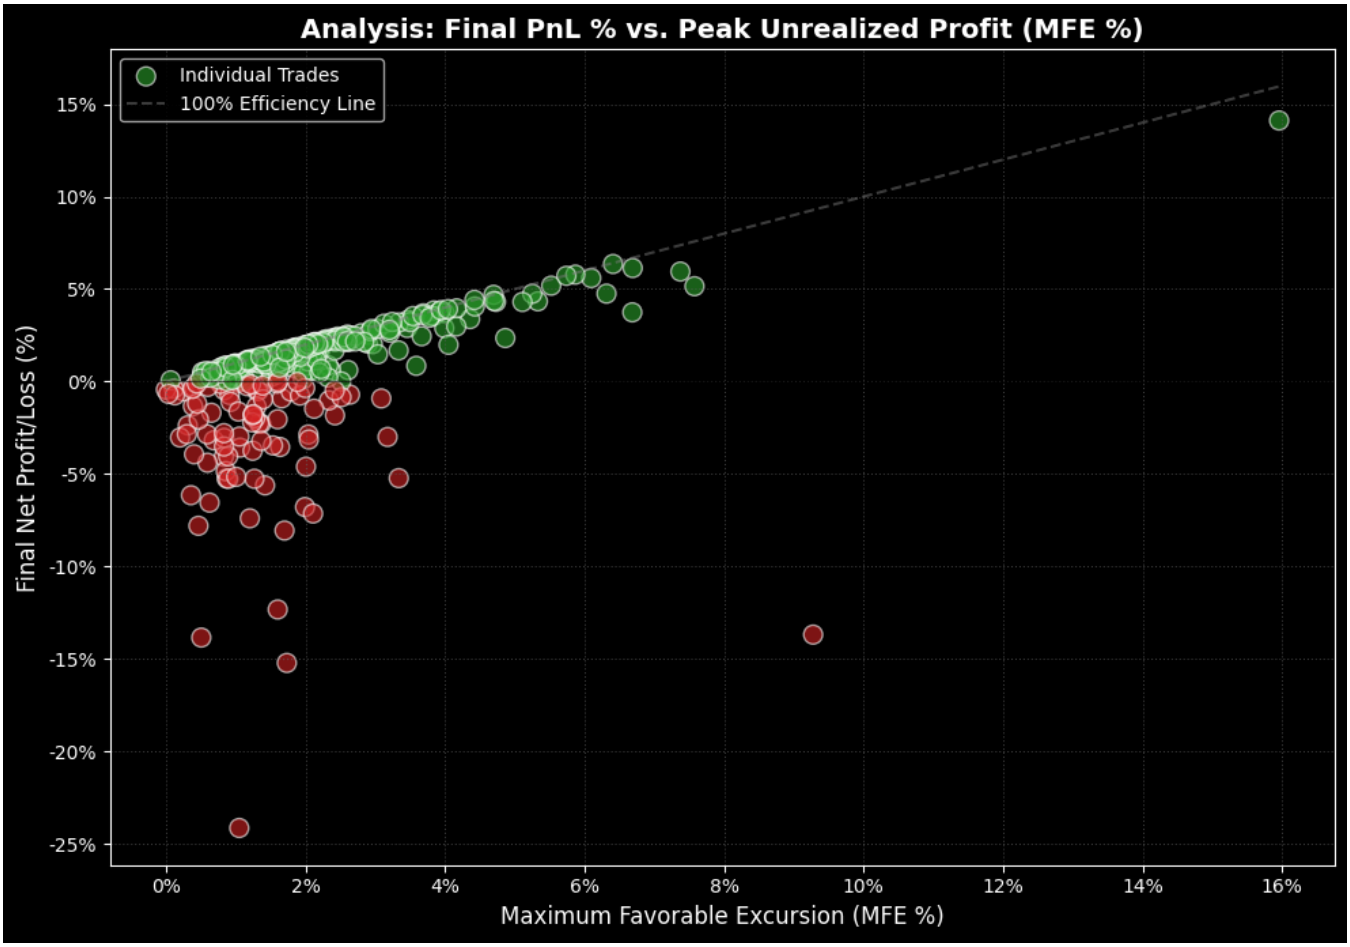
3. The Philosophy: The 'No Breathing Room' Reality

Perspective	Behaviour
The Human Error	After observing the 74% win rate, traders assume 'giving trades room to breathe' will capture more winners. The MAE chart shows this is a myth — winners move quickly and don't need room; losers that move far against you rarely recover.
The Data's Answer	There is a clear 'void' in the chart — no trades with MAE > -8% ever became meaningful winners. Every trade that fell more than 8% became a loser or break-even.
The Automation Edge	A hard stop at -7% to -8% would eliminate the worst canyon events without impacting a single meaningful winning trade.

SECTION SUMMARY *The PnL% vs MAE chart confirms the Inverse PSAR's risk structure: quick winners (MAE < -1.5%) and clean losers (MAE = PnL, PSAR exit triggers at or near the low). The critical insight is the 'void' at deep MAE levels — no trade with MAE worse than -8% ever recovered meaningfully, supporting a hard stop-loss in the -7% to -8% range.*

MFE Analysis (PnL% vs MFE)

The PnL% vs. MFE chart for the Inverse PSAR is the 'Capture Efficiency' map. While the MAE chart measured how much pain you absorbed, this chart shows how much of each trade's potential gain you actually kept — versus how much you 'gave back' as the PSAR naturally lagged the exit.



PnL% vs. MFE — The "Capture Ratio"

1. The General Concept

Axis / Element	Definition
X-Axis (MFE)	The peak profit the trade reached at its highest point
Y-Axis (PnL%)	The final realised profit when the trade was closed
45-Degree Line	Perfect capture — exited at the exact top of the trade
Vertical Distance	The 'Give-Back' — profit that was on screen but lost before PSAR triggered exit

2. Key Findings

Trade Type	MFE Range	PnL Range	Pro Take
'High Capture' Winners	~8% to 14%	~7% to 14%	Strong trades where the PSAR exit triggered near the peak — the strategy's best-case scenario.
'Typical' Winners	~2% to 5%	~1% to 3%	Standard mean-reversion trade: quick pop followed by PSAR flip exit. Modest give-back.
'Whipsaw' Cluster	~0.5% to 2%	-1% to -2%	Trades that peeked into profit territory before the market reversed. Classic false-positive entries.

3. The Philosophy: The Short-Cycle Exit Reality

Perspective	Behaviour
The Human Error	After watching a trade reach +5% and then exit at +2%, traders want to 'improve' the exit by using a tighter trailing stop. But tightening the exit increases the whipsaw rate — removing winning trades that temporarily pull back before continuing higher.
The Data's Answer	The average MFE of 2.01% vs average PnL of 0.50% shows a give-back of ~1.5%. This is the 'Cost of Certainty' — waiting for the PSAR flip confirmation means giving back some peak profit in exchange for an objective, mechanical exit.
The Automation Edge	The algorithm accepts this give-back as part of the system design. Attempting to optimise the exit typically introduces curve-fitting that reduces out-of-sample performance.

Note on Notional Reporting

Reporting Method	Description
Notional Reporting	Charts show percentage returns on $100,000 starting capital, keeping all trade sizes equal. This allows fair comparison of signal quality from 2000 vs. 2024 without the distortion of compounding on a much larger account.
Real World Results	In the Equity Curve, every penny is reinvested — which is how the initial $100,000 grew to approximately $446,490.

SECTION SUMMARY *The PnL% vs MFE chart reveals the Inverse PSAR's capture efficiency. With average MFE of 2.01% and average PnL of 0.50%, the strategy gives back ~1.5% per trade as the 'Cost of Certainty.' The whipsaw cluster (small MFE, negative PnL) represents the unavoidable noise of a contrarian entry system on an underlying that has genuine trend components.*

Three-way Comparison vs Buy and Hold

This is the 'Showdown' chart. The Three-way Comparison plots the Inverse PSAR Strategy, the Buy & Hold benchmark, and the Drawdown profiles side by side. For a contrarian strategy, this benchmark comparison reveals a fundamentally different value proposition than a trend-following system.

Interest from Idle Cash: Unlike trend-following strategies that spend significant time in cash, the Inverse PSAR is typically in the market for ~11 days at a time and in cash for shorter periods. However, the principle of Meb Faber's QTAA — parking idle cash into T-bills to earn collateral yield — remains applicable during the gaps between PSAR flip signals.

Three-way Comparison — The "Benchmark Battle"

1. The General Concept

Panel	Content
Top Panel (Equity Curves)	Compares the growth of $100,000 in the Inverse PSAR strategy versus $100,000 in a passive S&P 500 Buy & Hold position, with optional T-Bill yield on idle cash
Bottom Panel (Drawdown)	Compares the percentage underwater for both — showing where each strategy is most vulnerable

2. The Three Battlegrounds

Battleground A: The Bear Markets (2000–2003 & 2008)

Metric	Inverse PSAR Strategy	Buy & Hold (S&P 500)
Performance	Exposed — continues entering during decline	Plummeted ~-50%
Capital Position	Active but damaged by canyon losses	Praying for recovery

Pro Take: This is the Inverse PSAR's primary weakness. Unlike the SMA200 which moved to cash, this strategy kept entering — accumulating losses as each PSAR flip continued lower. Risk management and stop-losses are the critical mitigant during these periods.

Battleground B: The Vertical Bull (2013–2019)

Metric	Inverse PSAR Strategy	Buy & Hold (S&P 500)
Performance	Competitive — high win rate harvests consistent gains	Pulling ahead gradually

Pro Take: In this ideal regime, the Inverse PSAR approaches Buy & Hold performance with significantly more active management. The frequent winning trades compound steadily during smooth bull markets.

Battleground C: The Drawdown Comparison

Metric	Inverse PSAR Strategy	Buy & Hold (S&P 500)
Max Drawdown	-32.93%	Hits -50% twice
Professional Impact	Survivable but requires discipline	Gets you fired

3. The Philosophy: 'Winning Differently'

Perspective	Behaviour
The Human Error	Retail traders compare the equity curves and get frustrated when the strategy lags B&H during extended bull markets. They want to 'optimise' by changing the PSAR parameters.
The Automation Edge	The algorithm understands it's playing a different game: frequent, small gains with defined exits versus riding large positions through high volatility.
The Math	To recover from -50%, you need +100%. To recover from -32.93%, you need +49%. Still painful, but meaningfully better than unmanaged Buy & Hold.

SECTION SUMMARY *The Three-way Comparison shows the Inverse PSAR's mixed benchmark profile: competitive during bull markets, vulnerable during sustained downtrends. Its max drawdown of -32.93% is better than Buy & Hold's -50%+ but worse than the SMA200's -29.25%. The strategy's real edge is in the bull market regime — where it harvests consistent small wins from a high-frequency, mean-reversion approach.*

Monte Carlo Summary Table (Bootstrap Trades)

The Monte Carlo Summary Table (10,000 Bootstrap simulations) stress-tests whether the Inverse PSAR's 25-year performance is robust or the product of lucky timing and trade sequencing. Given this strategy's **negative payoff ratio** (losses larger than wins on average), sequence risk — particularly early canyon losses — is a critical concern.

Monte Carlo Simulation Summary

Inverse PSAR Strategy

10,000 Monte Carlo simulations, projecting potential final capital and risk scenarios over a 25-year period based on trade randomisation.

1. Distribution of Final Equity

Percentile	Final Capital (USD)	Interpretation
5th (Worst Case)	$159,058	Still in profit from $100k starting capital — moderate robustness with 1.1% probability of loss.
25th	$296,531	Conservative outcome; capital has roughly tripled despite adverse trade sequencing.
50th (Median)	$450,481	Close to actual backtest result ($446,490) — confirms the historical run was not an outlier.
75th	$673,395	Favourable outcome; consistent early wins compound strongly.
95th (Best Case)	$1,202,567	The high-frequency 'fat tail' — perfect sequencing with the 336 trades generates millionaire-level compounding.

2. Monte Carlo Risk Analysis (Max Drawdown)

Percentile	Max Drawdown (%)	Risk Level
95th (Best Case)	-19.08%	Minimum drawdown in lucky sequences — plan around the median, not this figure.
50th (Median)	-32.33%	Consistent with the historical backtest of -32.93% — validates the realism of the backtested result.
5th (Worst Case)	-52.66%	The true worst-case capitalisation scenario — deeper than the S&P 500's average bear market due to persistent canyon events clustering.

Monte Carlo Simulation — The "Alternate Universes" Test

1. What is a Monte Carlo Bootstrap?

Imagine taking all 336 trades, putting them in a hat, and drawing them out one by one to create a 'new' 25-year history. Repeat this 10,000 times.

Aspect	Description
The Goal	To see the range of possible outcomes — the Best Case, Worst Case, and Most Likely Case (Median).
The 'Bootstrap'	We sample your actual trade results with replacement, preserving the statistical DNA of the strategy (win rate, average win/loss) while shuffling the sequence.

2. Key Percentile Analysis

Percentile	Description	What to Look For
5th Percentile	The 'Unlucky' Outcome	Still in profit ($159k from $100k) — but 1.1% probability of loss reflects the negative payoff ratio risk
Median (50th Percentile)	The 'Real' Expected Outcome	Close to actual backtest ($446k vs $450k) — confirms result is not a sequence-of-returns anomaly
Standard Deviation	Consistency of Returns	Wide range ($159k to $1.2M) = 'High Variance Engine' typical of negative-payoff-ratio systems with high frequency

The 1.1% probability of loss across 10,000 simulations is the key risk metric. While 98.9% of simulated futures show profit, this is lower robustness than the SMA200's near-0% loss probability — a direct consequence of the strategy's asymmetric loss structure.

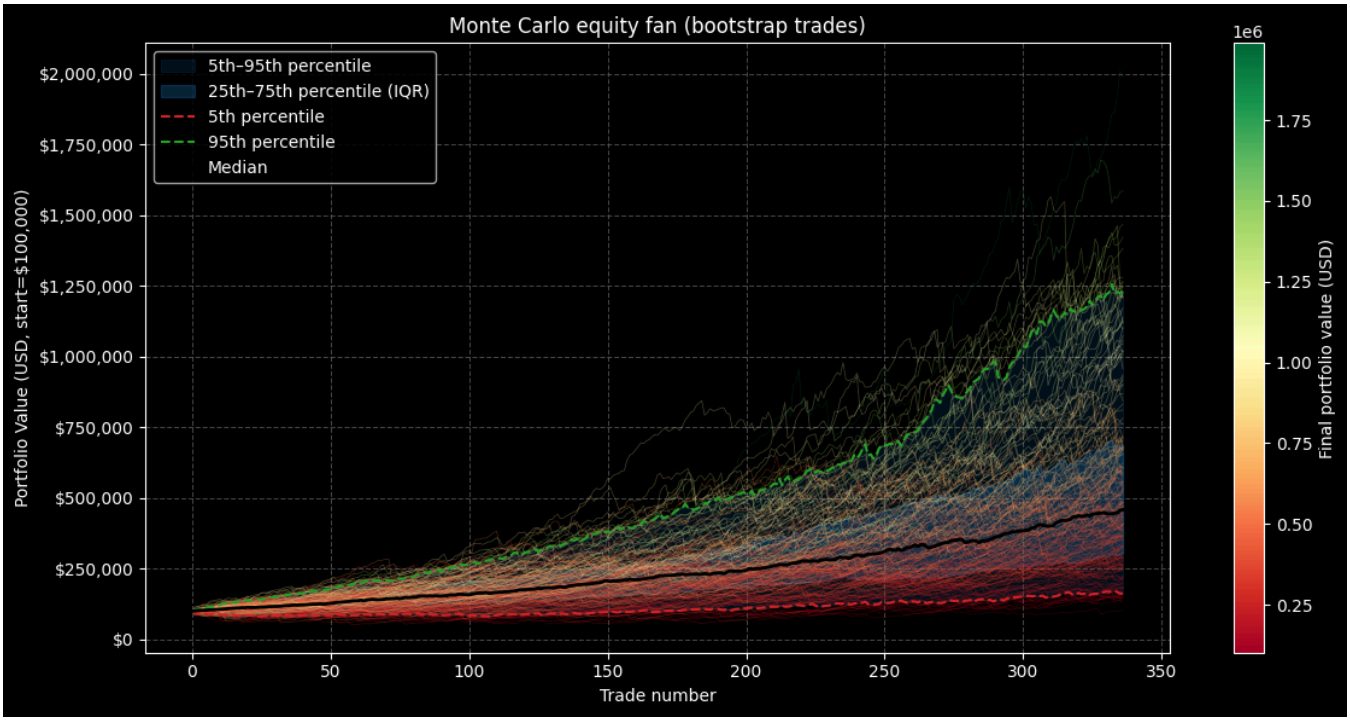
3. The Philosophy: Sequence Risk in a High-Frequency System

Perspective	Behaviour
The Human Error	A trader starts this strategy and hits the worst-case 5th percentile — early canyon losses cluster, account drops to $70k before recovering. Most human traders quit at this point.
The Automation Edge	The Monte Carlo table proves that the worst-case starting sequence is statistically rare (5%) but mathematically survivable ($159k end result). The bot continues executing.

SECTION SUMMARY *The Monte Carlo simulation (10,000 bootstrap runs) shows the Inverse PSAR's median outcome of $450,481 closely matches the actual backtest — confirming robustness. The 5th percentile outcome of $159,058 (still profitable) shows moderate resilience, while the 1.1% probability of loss reflects the negative payoff ratio risk. The wide outcome range ($159k to $1.2M) characterises this as a 'High Variance Engine' compared to more defensive systems.*

Monte Carlo Equity Fan

While the Summary Table was the 'Data Sheet' for risk, the Monte Carlo Equity Fan is the 'Probability Landscape' of future performance. For a high-frequency system like the Inverse PSAR, the fan has a distinctive shape driven by the **volume of trades** rather than the size of individual wins.



Monte Carlo Equity Fan — The "Cone of Uncertainty"

1. Fan Bands Definition

Band	Description
Median (50th Percentile)	The bold centre line — the 'Expected Case'
Inner Fan (25th–75th Percentile)	Where the strategy lives 50% of the time
Outer Fan (5th–95th Percentile)	The 'Stress Test' boundaries
The 'Widening'	Fan widens as randomness compounds over 336 trades — especially pronounced with a negative payoff ratio

2. Key Findings

Percentile	Final Wealth	Pro Take
5th Percentile (Worst Case)	~$159,000	Still profitable from $100k starting capital. The strategy does not destroy capital even in adverse sequences — a meaningful floor given the negative payoff ratio.
50th Percentile (Median)	~$450,000	The actual backtest result of $446,490 sits squarely in the heart of the distribution — your result was a 'Normal' outcome, not exceptional luck.

Percentile	Final Wealth	Pro Take
95th Percentile (Best Case)	>$1,200,000	The power of 336 high-frequency trades with positive mathematical expectancy, perfectly sequenced. Best-case outcome is life-changing compounding.

3. The Philosophy: Preparing for the 'Unlucky' Path

Perspective	Behaviour
The Human Error	Traders see the $1.2M top band and increase position size immediately. When they hit the 5th percentile — a cluster of early canyon losses — they face margin calls or permanent capital impairment.
The Automation Edge	The algorithm maintains consistent position sizing regardless of which 'fan path' it appears to be on. It understands that even the worst-case path eventually recovers.
The Discipline	Pre-commit to surviving the 5th percentile: 'If my account drops to $70,000 (from $100,000), I will NOT quit the strategy. I have pre-validated this as a statistical possibility, not a permanent failure.'

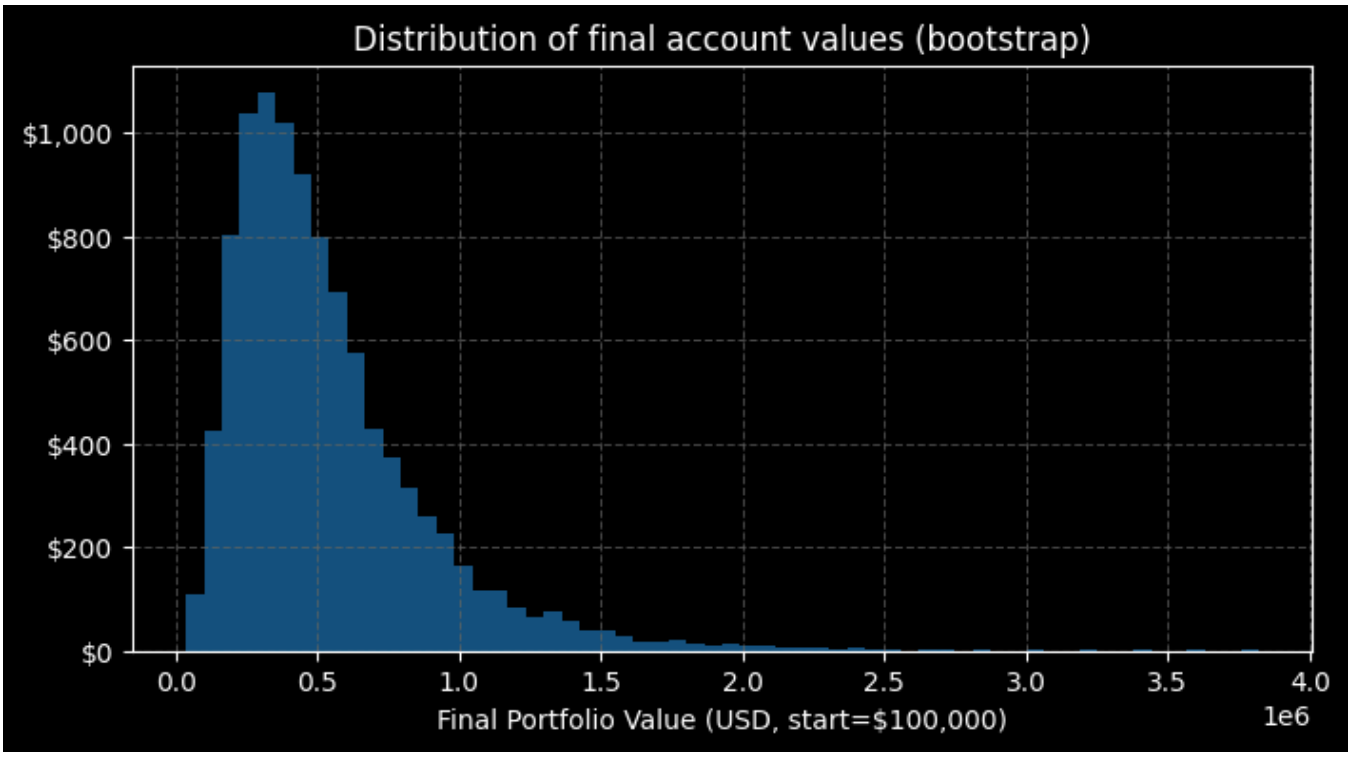
4. The Width of the Fan

Fan Width	Strategy Type
Wide Fan (Inverse PSAR)	'High Variance Accumulator' — driven by high trade volume with asymmetric loss risk. Canyon events can dramatically alter the path.
Narrow Fan	'Slow and Steady' — income-oriented, low-frequency defensive systems

SECTION SUMMARY *The Monte Carlo Equity Fan reveals 10,000 possible futures for the Inverse PSAR. Key insight: Even in the worst 5% of cases, the strategy remains profitable (~$159k from $100k). The actual result sits at the median — confirming the backtest was not outlier luck. The wide fan reflects the high-frequency, negative-payoff-ratio nature of the system, where trade sequencing significantly impacts the path.*

Distribution of Final Account Values (Histogram)

While the Equity Fan showed the journey, the Histogram shows the destination — the final tally across 10,000 alternate universes. For the Inverse PSAR, this distribution reveals a key structural difference from trend-following systems: the distribution is **right-skewed** but with a *less extreme left tail* than the SMA200, reflecting the strategy's high-frequency accumulation profile.



Distribution of Final Account Values — The "Wealth Map"

1. The General Concept

Element	Definition
X-Axis	The final account value across all 10,000 simulations
Y-Axis	How many times that specific outcome appeared
The Shape	Right-skewed distribution (Log-Normal), with the peak around the median value

2. Key Findings

Percentile	Final Value	Pro Take
5th Percentile (Worst Case)	~$159,000	Importantly, this is a profit not a loss. The strategy preserves capital in 98.9% of simulated outcomes — a meaningful but not exceptional floor.
50th Percentile (Median)	~$450,000	4.5× starting capital over 25 years, consistent with the historical result of $446,490. Validates the result as statistically typical for this strategy.

Percentile	Final Value	Pro Take
95th Percentile (Best Case)	>$1,200,000	Right-tail skewness: best-case exceeds median by ~$750,000, while worst-case is only ~$291,000 below median. Positive skewness confirms a survivable strategy.

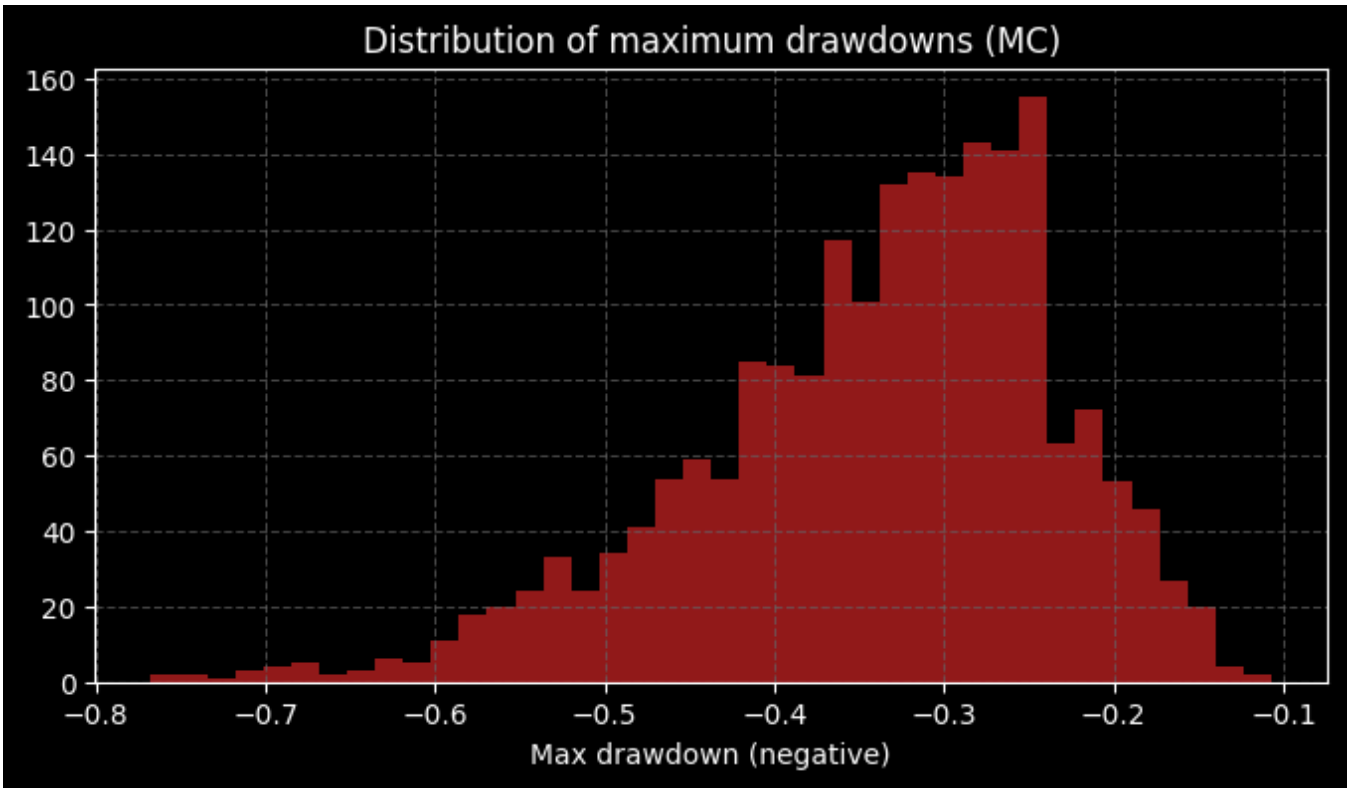
Key Characteristics of the Histogram

Characteristic	Description
'Partial Floor'	1.1% of simulations fell below starting capital — acceptable for a negative-payoff system
'Fat Right Tail'	Significant upside potential (>$1.2M in best cases) from compounding 336 trades
'Moderate Left Tail'	Some scenarios end below $200k, reflecting adverse clustering of canyon losses
'Median Gravity'	Most outcomes cluster around $400k-$500k, validating the historical $446k result

SECTION SUMMARY *The Final Account Value Histogram maps the Inverse PSAR's 'Wealth Landscape.' With 98.9% of simulations ending in profit and the median of ~$450k closely matching the historical result, the strategy demonstrates solid robustness. The 1.1% probability of loss reflects the structural risk of a negative-payoff system — manageable with proper position sizing but non-zero.*

Distribution of Maximum Drawdowns from MC Runs

While the histogram showed the wealth destination, this chart shows whether you can survive the journey. The Maximum Drawdown Distribution answers: 'What is the realistic range of worst-case account declines I should prepare for?' For the Inverse PSAR, this distribution is shaped by **canyon events** — the rare but severe losing trades that dominate the drawdown profile.



Maximum Drawdown Distribution — The "Breaking Point" Test

1. The General Concept

Element	Definition
X-Axis	The maximum drawdown percentage (e.g., -20%, -40%)
Y-Axis	The frequency of each drawdown level across 10,000 simulations
The Goal	To understand whether this strategy's drawdown profile is survivable for a real investor

2. Key Findings

Percentile	Drawdown	Pro Take
95th Percentile (Lucky)	~-19.08%	Only 5% of simulations had a max drawdown this shallow. Don't capitalise for this — it's a best-case scenario.

Percentile	Drawdown	Pro Take
50th Percentile (Median)	~-32.33%	The historical backtest's -32.93% aligns closely — confirming your actual experience was statistically normal, not unusually bad.
5th Percentile (Worst Case)	~-52.66%	The critical capitalisation threshold. In the worst 5% of trade sequences, canyon events cluster early. A -52.66% drawdown requires a 111% gain to recover — plan your position size around surviving this.

3. The Philosophy: The 'Canyon Cluster' Risk

Perspective	Behaviour
The Human Error	Seeing the historical -32.93% drawdown, most traders capitalise for -35% and feel comfortable. But the Monte Carlo 5th percentile is -52.66% — a scenario where several canyon events cluster early in the trading life.
The Automation Edge	The bot doesn't 'feel' a -52% drawdown differently than a -32% one. By capitalising for the 5th percentile scenario (not the historical median), the disciplined trader ensures survivability.
The Professional View	Position size = (Max Tolerable Account Loss) / (5th Percentile Max Drawdown). If you can tolerate a 25% account drawdown: position size = 25% / 52.66% = ~47.5% allocation to this strategy.

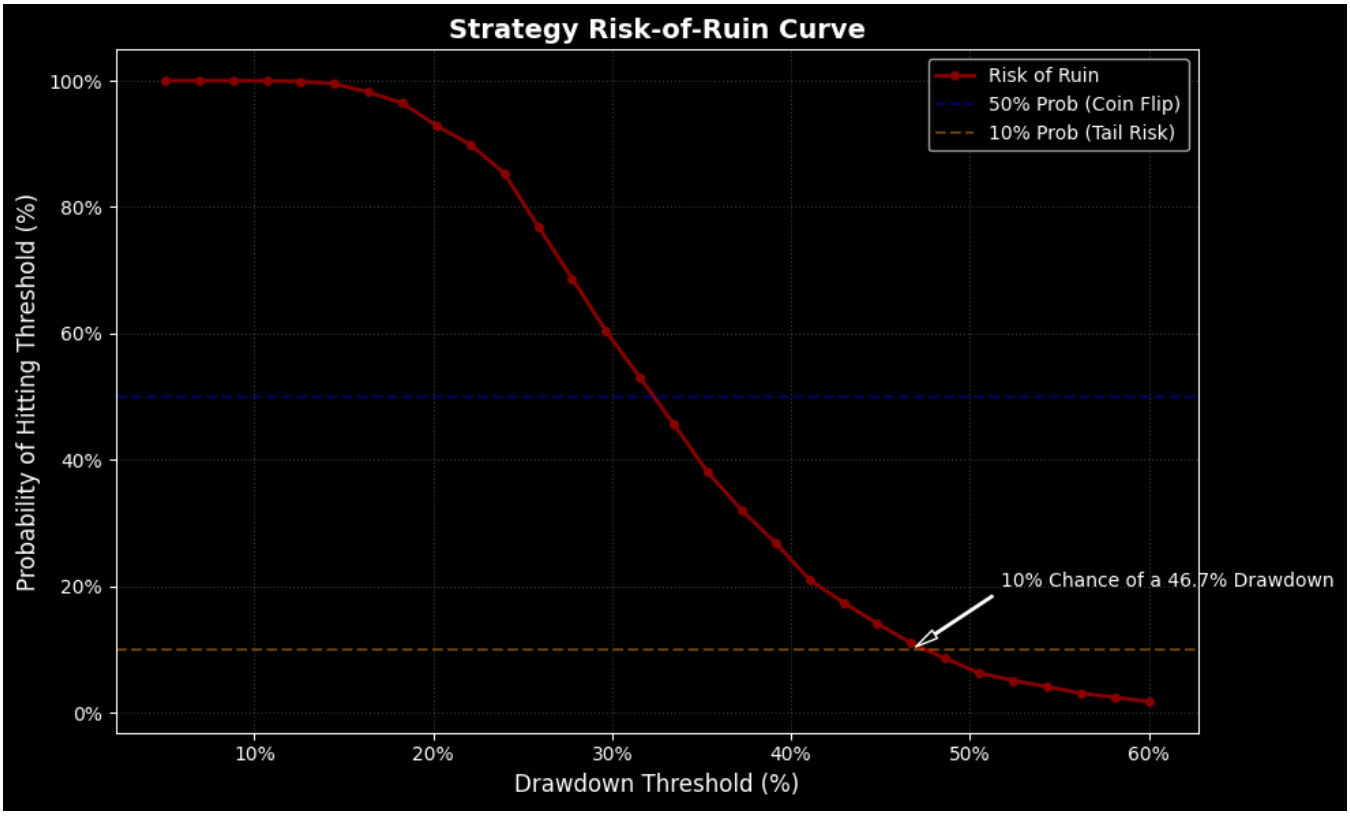
Summary Table

Metric	Value	Interpretation
Best Case (5% best)	-19.08%	Lucky scenario — don't plan around this
Median (50th)	-32.33%	Most likely drawdown you'll experience — matches historical
Worst Case (5% worst)	-52.66%	Canyon clustering scenario — use for position sizing
S&P 500 Comparison	-55%	Strategy keeps worst-case pain close to market's native risk

SECTION SUMMARY *The Maximum Drawdown Distribution confirms the Inverse PSAR's realistic drawdown profile: median -32.33% (matches historical -32.93%), with a tail-risk worst case of -52.66% from canyon event clustering. Professional position sizing should be calibrated to the 5th percentile, not the historical median, ensuring capital survives the statistical possibility of adverse trade sequencing.*

Risk-of-Ruin Analysis (Probability of Drawdown)

The Risk-of-Ruin Analysis is often the most misunderstood chart in a quantitative report. For the Inverse PSAR, this chart is especially important because the strategy's **negative payoff ratio** (losses 1.76× larger than wins) creates a distinct probability profile compared to systems where winners dominate.



Risk-of-Ruin — The "Probability of Pain"

1. How to Read This Chart

Element	Definition
Y-Axis (Probability)	Ranges from 0% to 100% — the likelihood of hitting a given drawdown level
X-Axis (Drawdown Threshold)	The levels of loss: 10%, 20%, 30%, 40%, 50%

If the line shows 85% at the '20%' X-axis mark, it means there is an 85% chance you will experience at least a 20% drawdown during your 25-year trading journey with this strategy. This is not a prediction of when — it's a probability statement about the journey.

2. The Three Danger Zones for the Inverse PSAR

Danger Zone	Drawdown Level	Probability	Pro Take
'Certainty Zone'	10%–20%	Near 90%–100%	Small drawdowns are almost guaranteed given the negative payoff ratio. These are 'Working Losses' — the overhead cost of a

Danger Zone	Drawdown Level	Probability	Pro Take
			high-frequency mean-reversion system. Plan for them, don't fear them.
'Strategy Stress Zone'	30%–40%	~20%–40%	This is where the PSAR's contrarian nature is stress-tested. A 30%+ drawdown signals a sustained bear market regime — the primary threat to this strategy. The probability is material, unlike the SMA200's steep drop-off.
'Ruin Zone'	50%+	~5%	Unlike the SMA200 (0% probability), the Inverse PSAR carries a small but non-zero probability of a 50%+ drawdown from canyon event clustering. This is the key distinction from a defensive trend-following system.

3. The Philosophy: Drawdown is Probabilistic, Not Predetermined

Perspective	Behaviour
The Human Error	A retail trader sees a 20% drawdown and assumes it will continue to 50% — confusing a statistical event with a trend. The Risk-of-Ruin chart shows that reaching 20% doesn't change the probability of reaching 40%; each level has its own independent probability.
The Automation Edge	The Risk-of-Ruin chart pre-loads the pain. By knowing before trading that a 30% drawdown has a ~20%-40% probability, the disciplined trader has already mentally processed this scenario and committed to continuing.
The 'Uncle Point'	Find your personal drawdown tolerance and check it against the chart. If 30% would cause you to stop the strategy — and there's a 20%-40% chance of experiencing that — you may need either a smaller allocation or a stop-loss rule that limits the maximum drawdown.

4. The Insurance Analogy

'If you drive regularly, there's a near-certainty of a minor accident (10% drawdown). There's a meaningful chance of a significant accident requiring major repairs (30% drawdown). But the probability of a total write-off (50%+ drawdown) is low but non-zero — unlike a more defensive strategy. Know these probabilities before getting behind the wheel.'

Key Takeaways

Concept	Insight
Certainty Zone	10-20% drawdowns are virtually certain — accept them as operational costs
Strategy Stress Zone	30% drawdown has ~20%-40% probability — plan psychologically for this
Ruin Zone	50%+ probability is ~5% — non-zero, unlike defensive trend followers; position size accordingly
Uncle Point	Know your personal pain threshold and match your allocation to the probability chart

SECTION SUMMARY *The Risk-of-Ruin chart reveals the Inverse PSAR's probability landscape: near-certain 10%-20% drawdowns, material ~20%-40% probability of reaching 30%, and a non-negligible ~5% chance of a 50%+ drawdown*

from canyon event clustering. This contrasts with the SMA200's near-zero 50%+ probability and defines the Inverse PSAR's key implementation requirement: active position sizing management tied to the 5th percentile worst-case scenario.

Inverse PSAR Backtest & Financial Analysis Conclusion

Performance Summary: Inverse PSAR Strategy (2000–2025)

The Inverse PSAR strategy presents a contrarian, mean-reversion case study: a system that wins 74% of the time but carries structural vulnerability to large adverse moves. A professional's focus is on the **asymmetric payoff structure** and what it implies for capital management.

Core Performance Metrics

Metric	Value
Time Period	2000–2025 (25 years)
Total Trades	336
Win Rate	73.81%
Profit Factor	1.60
Average Trade PnL	0.50%
Median Trade PnL	1.04%
CAGR	5.95%
Max Drawdown	-32.93%
Annualized Volatility	11.62%
Sharpe Ratio	0.56
Max Favorable Excursion (MFE)	2.01%
Max Adverse Excursion (MAE)	-2.81%
Time Underwater (by trade)	69.05%
Tail-Risk Drawdown (Worst 5%)	-52.66%

Key Professional Observations

1. Asymmetric Risk Profile (Reversed from SMA200)

While the SMA200 wins rarely but wins big, the Inverse PSAR **wins frequently but wins small**. The Profit Factor of 1.60 confirms positive mathematical expectancy, but the **Ratio of Avg Win to Avg Loss of 0.57x** means the system needs to win at least 64% of trades to break even — and it achieves 73.81%. This margin of safety above break-even (9.8 percentage points) is the strategy's core statistical buffer.

2. The 'Canyon Event' Risk

Data analysis reveals the strategy's primary vulnerability: a small number of large losing trades (MAE > -10%) drive a disproportionate share of total losses. The worst single trade lost -24.13%. **A hard stop-loss at -7% to -8% would eliminate the canyon events without impacting winning trade flow**, representing the single highest-impact improvement available.

3. System Sustainability and Statistical Significance

With **336 trades** over a 25-year window, this is **highly statistically significant** — approximately 4× more trades than the SMA200. The large sample size makes the 73.81% win rate and 1.60 Profit Factor extremely unlikely to be sampling artefacts.

4. The Regime Dependency

The strategy's most important practical characteristic is its **regime sensitivity**. In bull markets, the S&P 500's upward bias makes PSAR bearish flips temporary and profitable. In sustained bear markets (2000-2003, 2008), the same PSAR flips are 'correct' and losses accumulate. A simple regime filter — such as the 200-day SMA — could significantly improve risk-adjusted performance.

The Statistical Engine: Consistency Over Power

The most striking characteristic is the **Win Rate of 73.81%** combined with a Profit Factor of only 1.60. This creates a 'high-frequency treadmill' dynamic: the strategy must keep generating wins at this rate because each individual loss outweighs the average individual gain by 1.76×.

> *In essence: The strategy 'earns' consistent small increments through the noise of frequent PSAR flips, but must defend against the signal — the genuine trend changes that the PSAR is correctly identifying.*

Risk Management: The Core Implementation Requirement

A professional classifies this as a **'High-Frequency Contrarian'** system, not a defensive strategy.

Comparison	Inverse PSAR Strategy	S&P 500 Benchmark
Max Drawdown	-32.93%	>-50% (historical collapses)
Annualized Volatility	11.62%	~16% (2/3 higher)
Tail-Risk Drawdown (Worst 5%)	-52.66%	Similar magnitude

The 10,000-run Monte Carlo simulation is critical here: while the historical max drawdown was -32.93%, the simulation warns of a **-52.66% tail-risk drawdown** in the worst 5% of cases. An institutional trader would capitalise based on this figure — not the historical median.

Operational Recommendations

Three modifications would materially improve real-world performance without introducing curve-fitting:

- **Hard Stop-Loss at -7% to -8%** MAE analysis confirms zero winning trades had MAE worse than -8%. This stops canyon events cold.
- **Regime Filter (200-day SMA)** Only take PSAR flip entries when the S&P 500 is above its 200-day SMA. This eliminates the primary source of sustained bear-market losses.
- **Idle Cash in T-Bills** During periods between trades, sweep idle capital into short-duration government bills to capture collateral yield (following Meb Faber's QTAA principle).

Final Verdict

> *This strategy functions as a 'High-Frequency Toll Booth' — collecting small fees from the market's mean-reversion tendency, with occasional large payments in the opposite direction when the trend proves genuine.*

It is designed for a trader who prefers *activity and consistency* over *patience and concentration*. Success requires three disciplines: fixed position sizing, a hard stop-loss rule, and the psychological resilience to continue entering PSAR longs after experiencing canyon-event losses.

Classification	Analysis Period	Asset Class
High-Frequency Contrarian Mean-Reversion Strategy Analysis	2000–2025	S&P 500

SECTION SUMMARY *The Inverse PSAR strategy delivers a CAGR of 5.95% with a 73.81% win rate across 336 trades over 25 years. Its structural edge — the S&P 500's mean-reversion tendency after PSAR bearish flips — is statistically robust but regime-dependent. Three implementation improvements (hard stop-loss, regime filter, T-bill sweep) would materially enhance risk-adjusted returns. The strategy is best suited to systematic traders who prioritise trade frequency and win consistency over low-frequency, high-magnitude trend capture.*
