Keltner Bands Strategy

Backtest, Analysis & Notebook

S&P 500 | 2000–2025 | 25-Year Analysis

A comprehensive guide to the Keltner Bands mean-reversion strategy — covering entry logic, risk metrics, Monte Carlo simulation, and professional execution insights.

Disclaimer

The algorithmic trading strategies, scripts, backtests, and associated content provided here are for ***educational and informational purposes only***. They do not constitute financial advice, investment advice, trading advice, or a solicitation to buy or sell any security, cryptocurrency, or derivative instrument.

Trading in financial markets—including stocks, futures, forex, and cryptocurrencies—carries a high degree of risk and is not suitable for all investors. Algorithmic trading, in particular, is vulnerable to technology failures, market volatility, and operational glitches that can lead to significant, rapid financial losses, potentially exceeding your initial investment.

Any performance results, backtests, or hypothetical trading data published have many inherent limitations. Results are often calculated with the benefit of hindsight. Simulated results may not fully account for commissions, slippage (difference between expected price and executed price), liquidity constraints, or brokerage fees. Hypothetical performance does not guarantee future results. Past performance is not indicative of future performance.

AI was used extensively in the whole process and hallucinations can be attributed to both the AI and myself.

What is the Keltner Bands Strategy?

The Keltner Bands Strategy is a mean-reversion approach that exploits the tendency of the S&P 500 to "snap back" after short-term extremes. Unlike trend-following systems that ride multi-month moves, this strategy targets rapid recoveries from oversold conditions — typically completing a round-trip in under two weeks.

Keltner Channels were developed before John Bollinger popularised Bollinger Bands. Introduced in the 1960s and named after their innovator Chester Keltner, both families of indicators are based on volatility and use three separate lines — a middle line setting the basis for upper and lower bands — expanding and contracting as the Average True Range (ATR), or volatility, increases or decreases.

A key difference between Keltner and Bollinger Bands lies in the middle line: the Keltner middle line shows the "typical price" — the sum of the high, low, and close divided by three — while Bollinger Bands use only the closing price.

In this backtest we use the following settings: a 6-day period and 1.3 ATR multiplier, applied to the S&P 500 on a daily bar chart.

The Core Concept

Condition	Action
Price closes BELOW the Lower Keltner Band	BUY — Market is in short-term oversold territory
Price closes ABOVE the Typical Price (midline)	EXIT — Mean reversion is complete

> *Think of the Keltner lower band as an "elastic band floor." When price is stretched this far below the typical price, the rubber band snaps back — and this strategy is designed to hold that position until the midline is reclaimed.*

Why Keltner Bands?

The 6-day Keltner Channel with 1.3 ATR is calibrated to capture short-term oversold extremes. The settings are tight enough to generate a meaningful number of signals (337 trades over 25 years — roughly 13 trades per year) while filtering out minor intra-day dips. The "typical price" exit is elegant: it does not require the market to fully recover, just to reach a neutral mid-point.

Entry Logic

When do we ENTER a trade?

Step	Condition
1	Monitor the S&P 500 daily
2	Closing price closes BELOW the lower Keltner band
3	If YES → Enter a LONG position at the next day's open
4	If NO → Stay in cash

> *Example: S&P 500 Close: $4,050 | Lower Keltner Band: $4,100 | Result: $4,050 < $4,100 → SIGNAL: BUY*

Exit Logic

When do we EXIT a trade?

Step	Condition
1	Continue monitoring the position daily
2	Check if the closing price crosses ABOVE the typical price (HL/3 midline)
3	If YES → Exit the position at the close
4	If NO → Hold the position

> *Example: S&P 500 Close: $4,150 | Typical Price: $4,130 | Result: $4,150 > $4,130 → SIGNAL: SELL*

Key Definitions

Term	Definition
Keltner Channel	Volatility-based envelope comprising upper, middle (typical), and lower bands
Typical Price	(High + Low + Close) / 3 — the geometric centre of a daily candle
ATR (Average True Range)	A measure of daily price volatility over a rolling window
Lower Band	Typical Price − (1.3 × ATR) — the oversold threshold for entries
Mean Reversion	The tendency of price to return toward its average after an extreme move
Long Position	Buying an asset expecting it to rise back toward the mean
Drawdown	The decline from peak to trough in your account value
Whipsaw	When price briefly closes below the band but fails to revert, generating a loss

How This Strategy Works

1. Exploits Short-Term Fear

The S&P 500 frequently overreacts to short-term news. When price pierces the lower Keltner band, it signals that sellers have temporarily overwhelmed buyers. Historically, the index tends to reclaim its typical price within days.

2. High Win Rate Design

Unlike trend-following systems that win rarely but win big, Keltner Bands targets high-frequency, high-accuracy outcomes. With a 73% win rate across 337 trades, this strategy wins almost three out of every four trades.

3. Simple & Objective

No subjective judgment — just follow the math:

Signal	Rule
Price < Lower Keltner Band	= Buy
Price > Typical Price	= Exit

Pros and Cons

Benefit	Cost
High win rate (~73%) — psychologically easier to hold	Lower avg win than SMA200 — each win is modest

Short average trade duration (~6.5 days)	Requires active monitoring — more trades to manage
Lower max drawdown than buy & hold	Vulnerable in prolonged trending markets
Emotion-free, rules-based entry and exit	Profit factor (1.75) lower than pure trend systems

Important Warnings

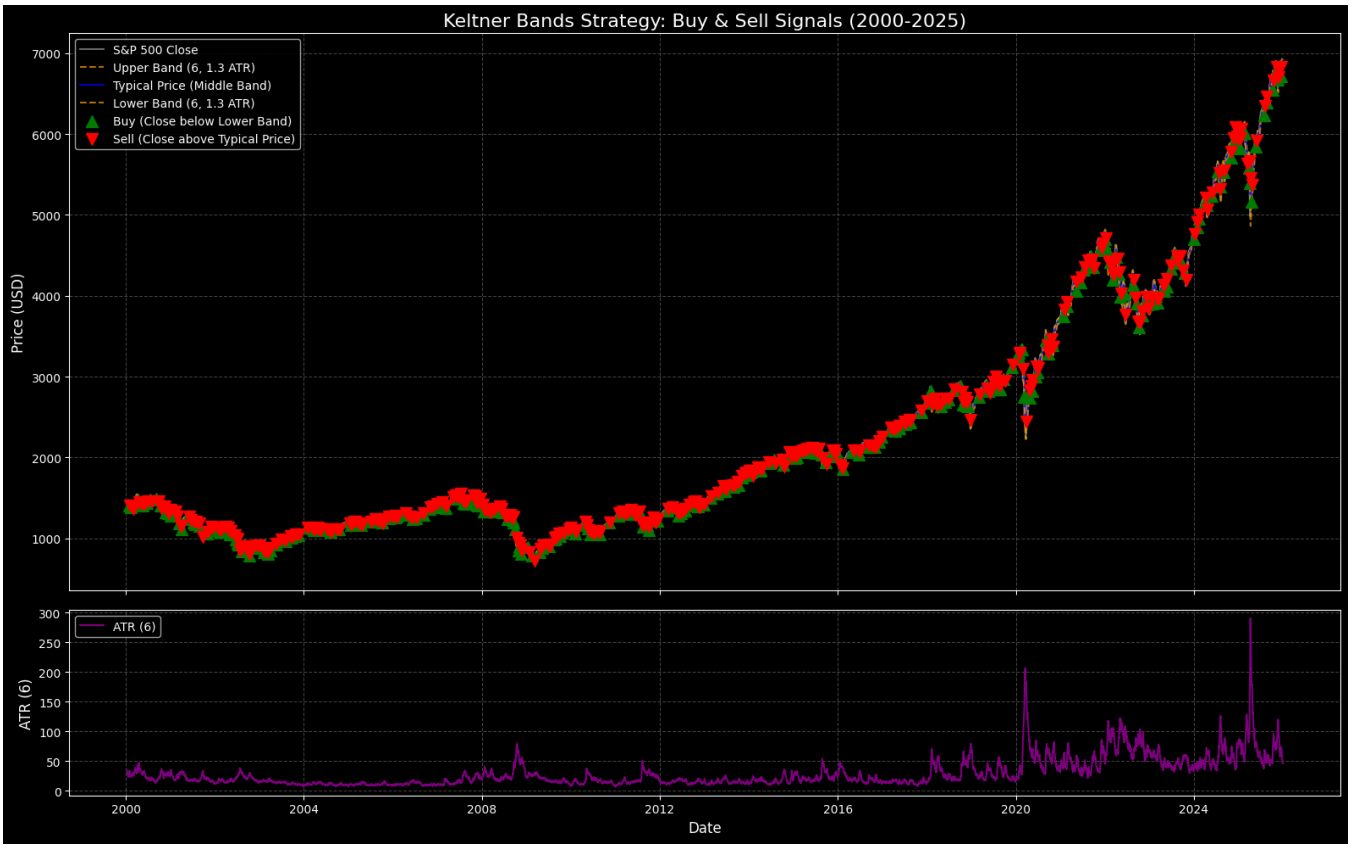
⚠ This Is NOT a High-Yield Strategy Per Trade

Expectation	Reality
Win 90%+ of trades	You win ~73% of trades
Each winner is large	Average winner is only 1.49%
Smooth daily returns	Occasional sharp -5% to -12% losing trades

⚠ A Single Big Loss Can Erase Many Wins

> *This is the structural risk. The strategy does not need to lose often — but when it does lose, the losses can be 3–8 times larger than the average win. One bad trade with an -11.87% loss offsets roughly 8 winning trades of +1.49%.*

SECTION SUMMARY The Keltner Bands strategy is a short-term mean-reversion system: buy when price closes below the lower Keltner Band (6-day period, 1.3 ATR), exit when it crosses above the typical price. It captures frequent small rebounds while accepting the risk of occasional large losses. Success requires discipline to hold through short-term adverse moves and to not over-leverage despite the high win rate.



Executive Summary: The "High Accuracy" Mean Reverter

Performance Summary: Keltner Bands Strategy (2000–2025)

This table consolidates the key performance metrics of the Keltner Bands mean-reversion strategy, including profitability, risk, and trade dynamics.

Category / Metric	Value	Professional Interpretation
CAGR	5.83%	Solid compound growth — better than the SMA200 (4.42%) on this dataset.
Annualized Return	6.06%	The average arithmetic yearly return of the strategy.
Profit Factor	1.75	Good but not exceptional. The system returned $1.75 for every $1.00 lost.
Max Drawdown	-20.49%	Standout result. Significantly shallower than the market's historical -50%+ crashes.
Annualized Vol	8.66%	Much lower than the S&P 500 (15–18%), offering a very smooth ride.
Sharpe Ratio	0.47	Decent risk-adjusted return — slightly better than the SMA200's 0.45.
Win Rate	73.00%	High-frequency, high-accuracy system — psychologically comfortable.
Avg Trade PnL	0.47%	Many small, consistent gains — the signature of mean reversion.
Num Trades	337	High-frequency sample size (~13 trades per year).

Comprehensive Performance Metrics

Metric	Value	USD $
Total Net Profit	334.20%	$334,200.07
Gross Profit	366.51%	$366,507.76
Gross Loss	-209.44%	-$209,436.12
Profit Factor	1.75	N/A
Max. Drawdown (Equity)	-20.49%	N/A
Sharpe Ratio	0.47	N/A
Sortino Ratio	0.33	N/A
Ulcer Index	0.0441	N/A
Kelly Criterion	31.28%	N/A
Total # of Trades	337	N/A
Percent Profitable	73.00%	N/A
# of Winning Trades	246	N/A
# of Losing Trades	91	N/A
# of Even Trades	0	N/A
Avg. Trade PnL	0.47%	$466.09
Avg. Winning Trade PnL	1.49%	$1,489.87
Avg. Losing Trade PnL	-2.30%	-$2,301.50
Ratio Avg. Win/Avg. Loss	0.65	N/A
Max. Consec. Winners	19	N/A
Max. Consec. Losers	4	N/A
Largest Winning Trade PnL	10.79%	$10,789.01
Largest Losing Trade PnL	-11.87%	-$11,866.17
Avg. # of Trades per Day	0.036	N/A
Avg. Time in Market	6.47 days	N/A
Profit per Month	1.08%	$505.32
Max. Time to Recover	40 trades	N/A
Avg. MAE	-2.30%	N/A
Avg. MFE	1.99%	N/A
Avg. ETD	1.52%	N/A

The Mathematical Engine: Positive Expectancy

For a retail investor, the Win Rate is often the most attractive-sounding metric. However, algo trading is a game of Expectancy.

The Formula

> *Expectancy = (Win % × Average Win) – (Loss % × Average Loss)*

The Mathematics

Component	Value
Win Rate	~73.0%
Loss Rate	~27.0%
Profit Factor	1.75
Average Trade PnL	0.47%

Even though the average win (+1.49%) is smaller than the average loss (-2.30%), the high win frequency keeps expectancy positive. This is the "Batting Average" math of mean reversion: you hit singles consistently, not home runs — but you hit them three-quarters of the time.

The Systematic Advantage: Overcoming the "Human Gap"

Why do most retail investors underperform where this algorithm succeeds? It comes down to Discipline and Consistency.

> *Behavioral finance shows that humans are hardwired to take profits too early (to "lock in" gains) and hold losses too long (hoping to avoid recognizing them).*

Advantage	Description
Precision	The algorithm applies the exact same rule — close below lower band, exit above typical price — every single time. A human trader would inevitably skip signals or add "extra confirmation."
Persistence	The algorithm doesn't get emotionally fatigued from running 337 trades over 25 years. Each trade is evaluated independently.

Strategy Identity: The "Opportunist"

In professional terms, this is a Short-Duration Mean-Reversion strategy.

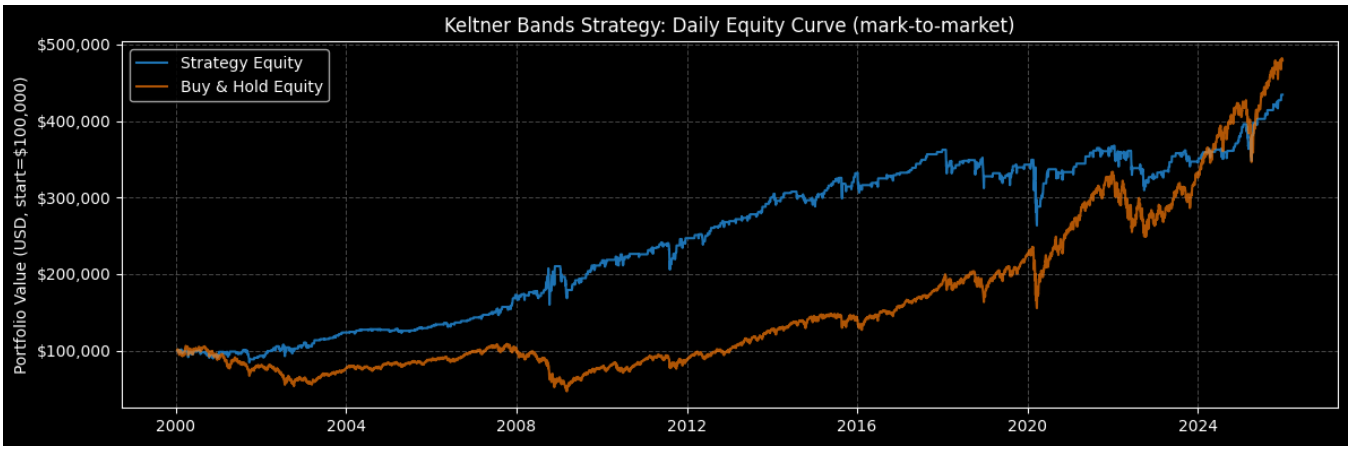
Metric	Value	Interpretation
CAGR	5.83%	Above-average returns for the risk taken
Max Drawdown	-20.5%	Shallow drawdown — capital stays largely intact
Win Rate	73.0%	High accuracy — manageable psychologically

> *You are not riding multi-year trends. You are repeatedly picking up dropped coins — small, fast, and frequent.*

SECTION SUMMARY This strategy functions as a "market rhythm harvester" — designed to capture the frequent short-term snap-backs of the S&P 500 through high win-rate mathematical expectancy and systematic discipline. The risk is not in the frequency of losses but in their size when they do occur.

The Daily Equity Curve

The Daily Equity Curve provides a direct comparison between the Keltner Bands strategy and a simple "Buy & Hold" approach for the S&P 500. This view shows the mark-to-market value of the account every single day.



The "Smoother Ride" Analysis

The Keltner Bands curve is characteristically "flat" for extended periods — reflecting the strategy's short in-market time (~38% of days). When the market experiences severe downturns, the strategy exits quickly (as soon as price recovers above the typical price or there is no new signal) and returns to cash.

The 2008 & 2000 Market Crises

Crisis Period	Buy & Hold (B&H)	Keltner Bands Strategy
2000 Dot-com Crash	>-50% collapse	Partially protected — short exposure windows
2008 Financial Crisis	>-50% collapse	Partially protected — rapid exits near typical price
2022 Bear Market	>-19%	Limited exposure — quick mean-reversion trades

> *Because trades are short-duration (average 6.5 days), the strategy is rarely caught holding through a multi-week trending decline. The mean-reversion exit rule closes the position as soon as the typical price is reclaimed.*

The Bull Market Participation

During sustained bull markets (e.g., 2013–2019, 2021), the Keltner Bands strategy continues to participate — capturing the frequent dips-and-recoveries that occur even within uptrends. The strategy earns during these periods by repeatedly buying the "intra-trend dips."

The Math: Risk-Adjusted Returns

Metric	Value	Interpretation
Sharpe Ratio	0.47	Modest but consistent risk-adjusted return
Annualized Volatility	8.66%	Significantly lower than the market

The Philosophy: The "Rhythm" of Mean Reversion

Short Flat Periods

There are weeks where the strategy generates no signals — no dip below the lower band. These flat periods represent the strategy "waiting for its pitch." The discipline is to resist forcing trades when the signal isn't there.

The Automation Edge

An algorithm never "gets bored" and invents reasons to trade. It is perfectly content to wait in cash for weeks if the lower band is not breached. This restraint is one of the primary sources of alpha.

2022: Short-Duration Resilience

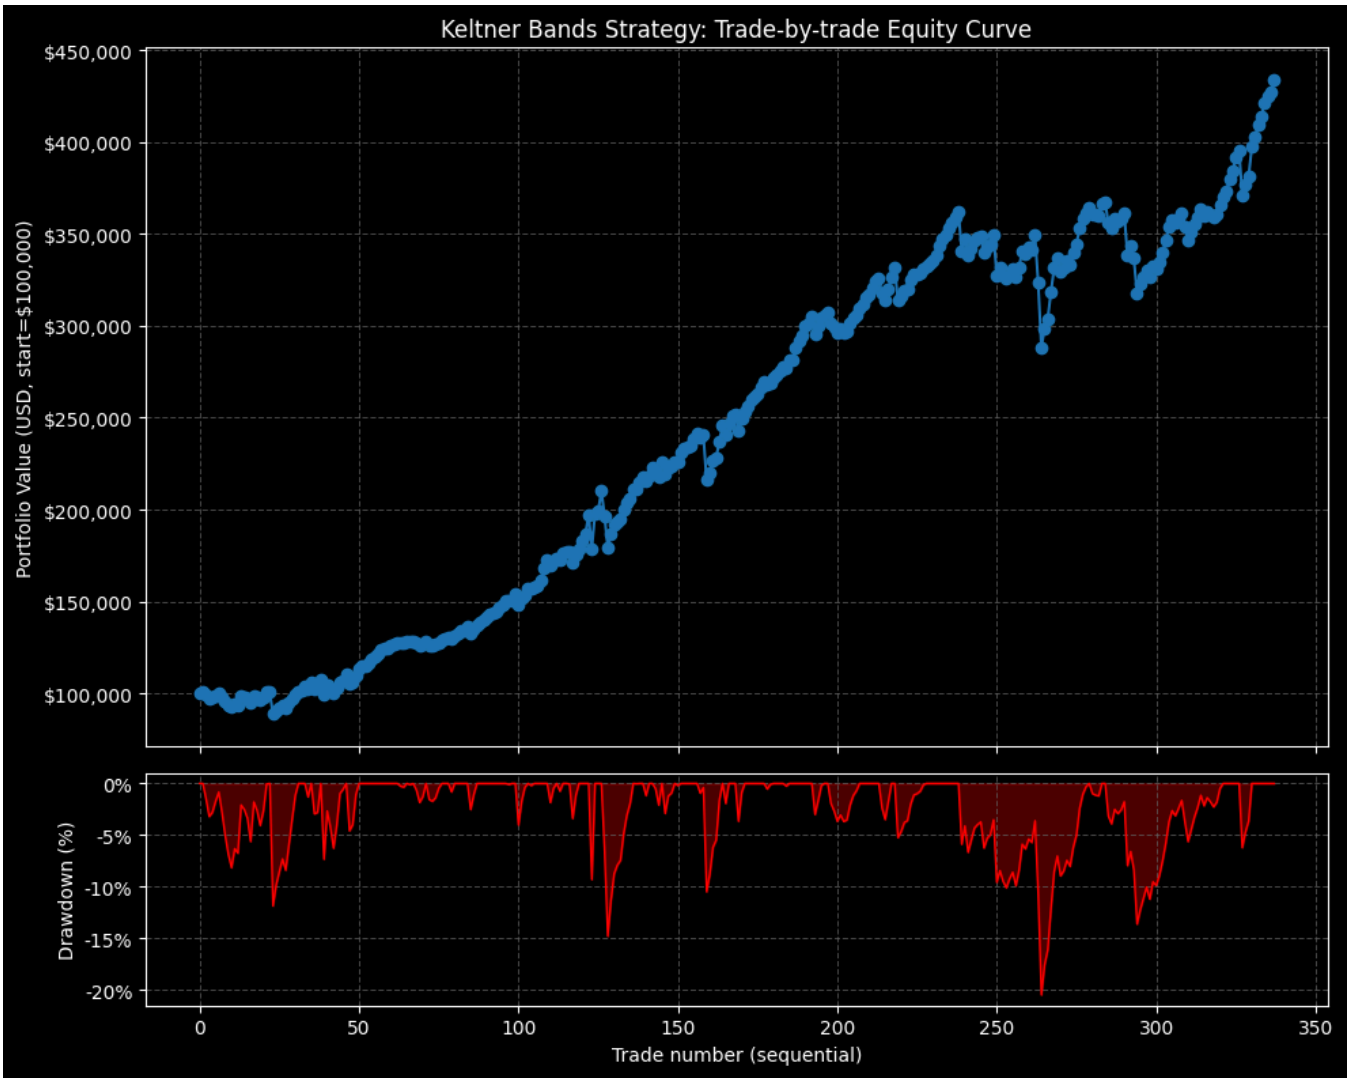
In 2022, when both stocks and bonds fell simultaneously, the Keltner Bands strategy maintained resilience through its short holding periods. Unlike trend-following systems that could have been caught long for months, each trade was resolved within days, limiting cumulative damage.

Asset Class	2022 Performance	Strategy Exposure
S&P 500 (Stocks)	~-19%	Short-term exposure only
Bloomberg Aggregate Bond Index	~-13%	Not applicable — equity only
Keltner Bands Strategy	Limited drawdown	Quick exits near typical price

SECTION SUMMARY The Daily Equity Curve demonstrates that the Keltner Bands strategy generates returns through short, frequent trades rather than sustained multi-month positions. The result is a smoother equity curve with lower volatility and shallower drawdowns compared to passive Buy & Hold.

Trade-by-Trade Equity Curve & Drawdown

While the Daily Equity Curve shows us the value of our account every day, the Trade-by-Trade Equity Curve shows us the strategy's "career" as a series of distinct decisions. For a professional trader, this is where the "truth" of a system lives.



Trade-by-Trade Analysis: The "Career" of a Mean Reverter

1. The Math: Sequential Compounding & High Win Frequency

Metric	Value
Total Trades	337
Winning Trades	246 (73%)
Losing Trades	91 (27%)
Starting Capital	$100,000
Final Value	$434,200

> *Starting with $100,000, the final portfolio grows to $434,200. This demonstrates that consistent small wins compound powerfully over time — even with a profit factor of only 1.75.*

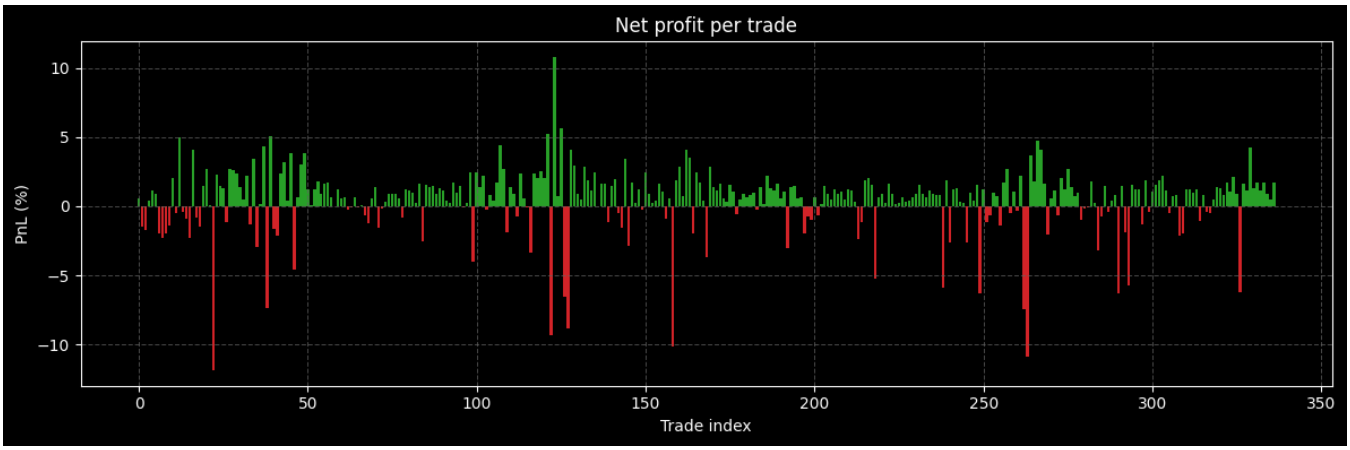
2. The Drawdown: Measuring the "Emotional Cost"

Metric	Value
Maximum Drawdown	-20.49%
Trough Value	~$79,510
Key Concern	Occasional large single-trade losses

> *For a retail investor, seeing your account dip by -20% is uncomfortable — but this is shallower than the SMA200's -29% and dramatically better than buy & hold's -50%+ historical crashes.*

3. The Philosophy: The "Bowling Average" Mindset

Perspective	Behavior
The Human Error	A trader with a 73% win rate tends to get overconfident and over-leverage. When a -10% losing trade hits, it feels catastrophically unfair. "I was right 73% of the time!" The problem is that each loss can erase ~7 average wins.
The Automation Edge	The algorithm doesn't remember its last 19 consecutive wins. It applies the same position sizing every trade, preventing the over-confidence trap.



Net Profit per Trade Analysis

1. The Math: The "Skewness" of Returns

Statistical Profile	Description
Distribution Type	Slight Negative Skew (rare large losses)
Win Rate	73.0%
Average Win	Consistently ~1.5%, rarely above 5%
Monster Losses	1–2 trades of -8% to -12% can heavily impact totals

> *Notice the consistent forest of small positive blue bars punctuated by occasional tall red spikes. The -11.87% losing trade is immediately visible — a single trade that reversed the gains from roughly 8 wins.*

2. The Philosophy: The "Single-Trade Ruin" Risk

Perspective	Behavior
The Human Error	High win rates breed complacency. Retail traders often see 73% accuracy and assume they can safely increase leverage 3x or 4x. A single -11% losing trade at high leverage can wipe out months of gains.
The Automation Edge	The algorithm enforces fixed position sizing. The 73% win rate never becomes a reason to increase risk.
The Professional Mindset	A pro trader looks at this chart and notes the "outlier" red bars — and asks: what market conditions created those? They stress-test the strategy under those conditions specifically.

3. Professional Observations: Why "Consistency" is the Story

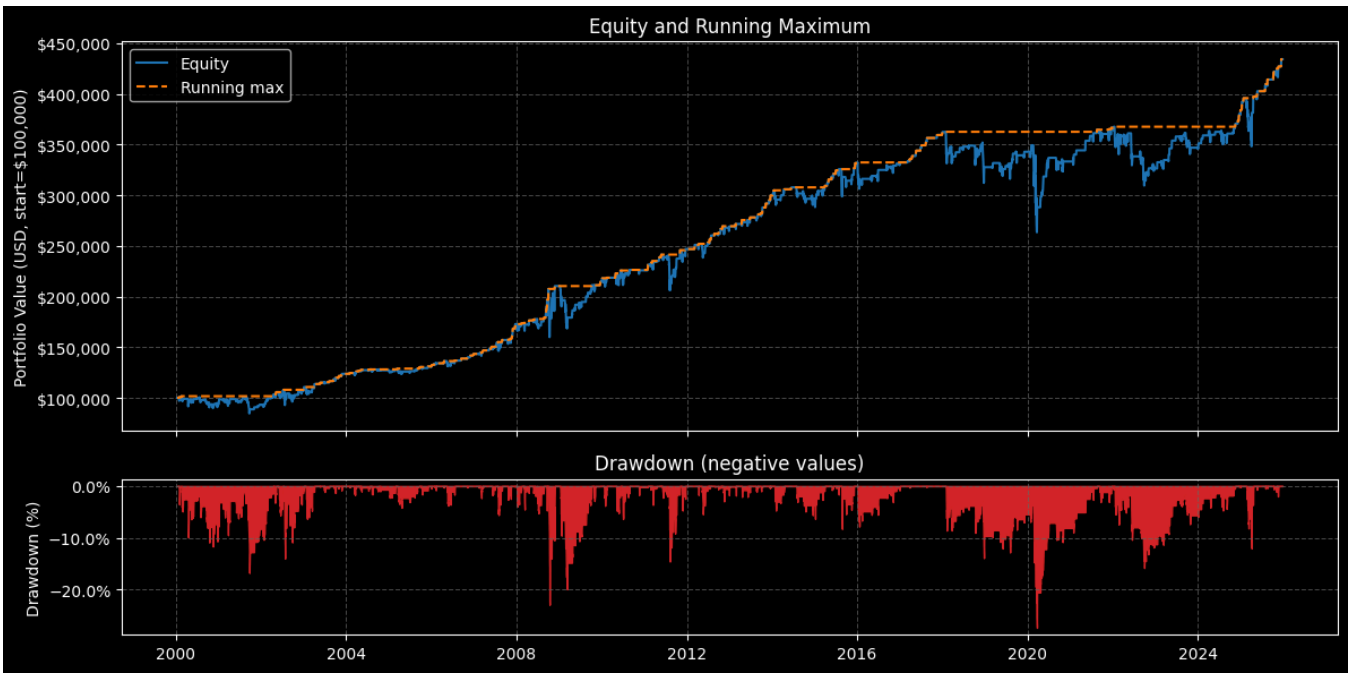
Observation	Interpretation
Win Uniformity	Most blue bars are roughly the same height — confirming the mean-reversion mechanism works consistently across 25 years.
Loss Outliers	The few tall red bars represent gap-down events where the market never reclaimed the typical price before falling further — the failure mode of mean reversion.

SECTION SUMMARY The Trade-by-Trade analysis reveals the true nature of mean reversion — high-frequency compounding of small wins punctuated by occasional sharp losses. Success requires consistent position sizing and the discipline to never over-leverage on the basis of historical win rate.

The Cumulative Maximum Drawdown

The Cumulative Maximum Drawdown chart is the "Stress Test" of your trading system. In professional quantitative finance, we look at the MAR: the CAGR divided by Max Drawdown. A professional focus on this chart covers two things: Depth and Duration.

> *MAR stands for Managed Account Reports. It is essentially an "Efficiency Score" that measures how much return you earned relative to the worst-case scenario you had to endure.*



The MAR Ratio (The "Pain-to-Gain" Metric)

1. The Math: Return per Unit of "Disaster"

> *MAR Ratio = Compound Annual Growth Rate (CAGR) / Maximum Drawdown*

Metric	Value
CAGR	5.83%
Maximum Drawdown	20.49%
MAR Ratio	0.28

In the world of professional hedge funds, a MAR of 0.5 to 1.0 is often the target. A MAR of 0.28 for a single-indicator retail strategy is respectable — notably higher than the SMA200's MAR of 0.15, reflecting the shallower drawdown of this mean-reversion approach.

> *It tells us that for every 1% of annual growth, you had to be willing to stomach about 3.5% of potential loss.*

2. The Philosophy: MAR vs. Sharpe

Metric	Weakness	Strength

Sharpe Ratio	Volatility can include "good" upward spikes. Sharpe penalises you for both.	Measures risk-adjusted returns using standard deviation
MAR Ratio	Ignores upside volatility entirely	Only cares about the Trough — survival at worst case

> *MAR asks: "If you invested at the absolute peak and held until the absolute bottom, could you survive?"*

3. Professional Take: The "Shallow Pool" Advantage

Role	Description
"Short-Duration Advantage"	Because each trade is resolved within days, the strategy rarely compounds losses across multiple trades in a trending market. Each new trade "resets" the loss clock.
Benchmark View	A Buy & Hold strategy on the S&P 500 has a MAR of approximately 0.10–0.12 historically (e.g., ~5% CAGR / 50% drawdown). The Keltner Bands MAR of 0.28 is approximately 2.5x more efficient at limiting the maximum pain.

Professional Advice: "The Sleep-at-Night Score"

MAR Level	Interpretation
High MAR (>0.5)	You are getting a lot of "growth" for very little "fear"
Moderate MAR (0.28)	Respectable for a single-indicator system — you earn meaningful returns while keeping drawdowns manageable

> *Ask yourself: "Is the 5.83% return worth the 20.49% drawdown to you?" For most retail investors, this ratio is comfortable — you are not being asked to stomach a -50% crash to earn moderate returns.*

The Anatomy of the Underwater Curve

1. The Math: The "Asymmetry of Recovery"

Metric	Value
Maximum Drawdown (Trough)	-20.49%
Recovery Gain Required	~26%
Comparison: 50% drop requires	100% gain to recover

> *To recover from a 20.49% drop, you need a ~26% gain on your remaining capital to get back to zero. Compare this to the S&P 500's Buy & Hold drawdown of over -50% in 2008 — a 50% drop requires a 100% gain to recover.*

2. The Running Max: The "High-Water Mark"

The gap between your current equity and the high-water mark is the "underwater" period. For this strategy, with its high trade frequency, the account recovers quickly — averaging 40 trades to recovery (roughly 3 months of activity).

3. The Philosophy: "Time Underwater"

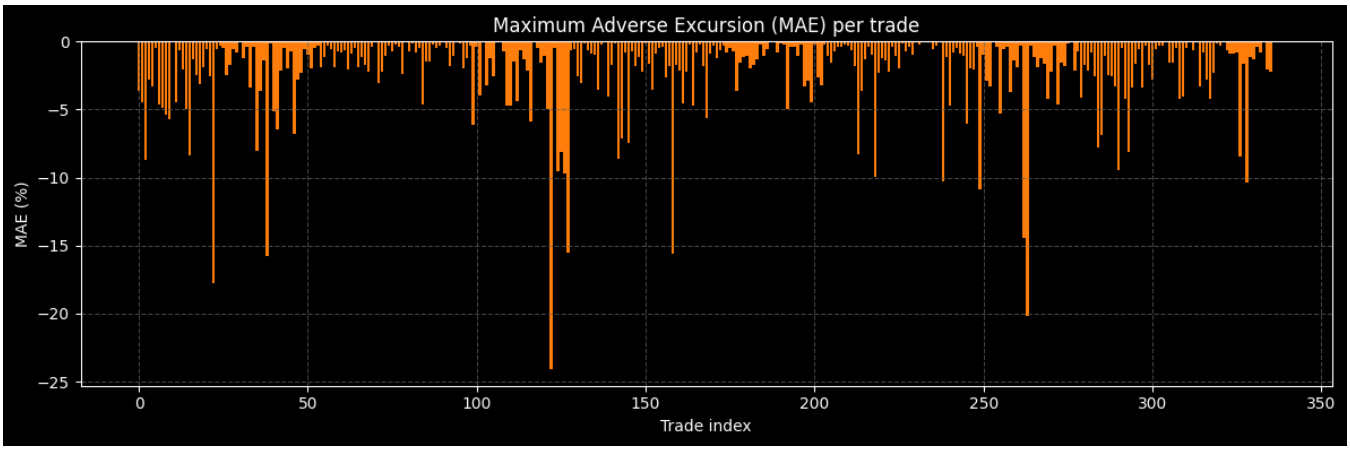
Perspective	Focus

Retail Investors	Focus on the depth of a crash
Professionals	Focus on the duration
Keltner Reality	Moderate flat-bottom periods — shorter than trend-following systems given the faster trade cadence
The Automation Edge	A bot doesn't care if it hasn't seen a new high in 50 trades. It simply waits for the next signal.

SECTION SUMMARY The MAR Ratio of 0.28 represents a mathematically efficient system compared to Buy & Hold. The true cost of trading is not the depth of drawdown (-20.49%) but the duration of time spent underwater. The short-duration nature of Keltner Bands trades accelerates recovery relative to longer-horizon systems.

MAE Bar Chart (Per Trade)

For a retail investor, understanding MAE (Maximum Adverse Excursion) is the difference between "guessing" where to put a stop-loss and "calculating" it like a professional. This chart shows the maximum drawdown experienced within each trade before it either resolved or was stopped.



MAE — The "Stress Meter"

1. The General Concept: What is MAE?

Think of MAE as a "Stress Meter". For every trade you take, the price rarely goes straight up. Usually it dips against you before (hopefully) snapping back toward the typical price. MAE measures that deepest dip during the trade.

> *The Analogy: If you're wading into the surf at the beach, the MAE is how deep the water gets before the wave pushes you back to shore. If a rogue wave hits (your stop-loss), the trade is over.*

2. Professional Analysis: Key Findings

Finding	Details
The "Shallow" Requirement	Most big winning trades had an MAE of less than -1.5%. Mean-reversion works best when the snap-back is immediate.
The Averaging MAE = Avg Loss	The average MAE (-2.30%) equals the average losing trade (-2.30%), confirming the SMA exit (typical price) acts as a natural "hard floor."
The Outlier Risk	The max MAE is -24.10% — a rare but real tail risk representing a scenario where price fell far below the lower band and never recovered to the typical price before a very large loss was booked.

> *This represents the "cost of the mean-reversion bet" — the risk that price continues trending down after the buy signal rather than reverting.*

3. The Philosophy: The "Rubber Band" Risk

A professional trader treats mean reversion like catching a falling knife — carefully and with a plan.

Perspective	Behavior
The Human Error	A retail trader sees a trade go -5% and thinks, "I'll wait for it to revert." But the data proves that once a Keltner trade hits -8%, it almost never generates a profit.

The Automation Edge	The bot respects the "Small Snap" Rule. By exiting at the typical price regardless of how large the intermediate dip was, it prevents a paper cut from becoming a permanent wound.

4. The -5% Hard-Stop Consideration

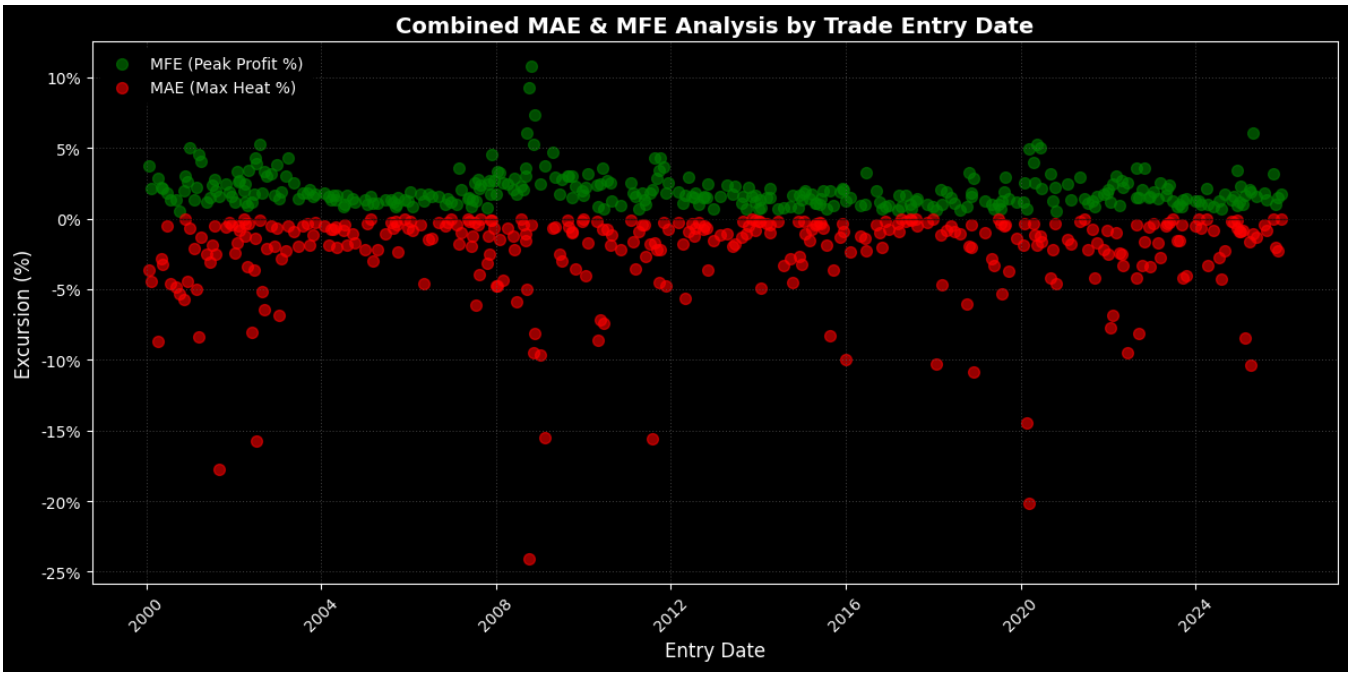
> *You could tell yourself that while the typical price is the primary exit, adding a "Hard Stop" at -5% would provide secondary protection against gap-down events or sustained trending moves, without accidentally killing most mean-reversion winners.*

Stop-Loss Level	Effect
-1.5% to -2.5%	Standard Keltner exit heat (typical winners)
-4% to -5%	Almost never recovers to winner territory
-5% Hard Stop	Safety net against gap-down events without killing typical winners

SECTION SUMMARY MAE analysis reveals the Keltner Bands strategy's unique "Risk Signature" — winning trades rarely dip below -1.5%, while losing trades cluster in the -2% to -5% range. The rare but large outlier losses (up to -24%) represent the primary tail risk. A -5% hard-stop rule as a secondary protection layer could reduce the impact of these outliers without sacrificing standard mean-reversion winners.

Combined MAE & MFE Scatter Chart by Entry Date

The Combined MAE & MFE Scatter Chart (by Entry Date) is the "Heart Monitor" of your strategy over time. This scatter chart shows when and how each trade's upside and downside excursions evolved across 25 years.



Combined MAE & MFE — The "Signal-to-Noise" Timeline

1. The General Concept

Marker	Definition
MFE (Maximum Favorable Excursion)	How high the profit went at its peak during the trade
MAE (Maximum Adverse Excursion)	How deep the loss went at its trough during the trade

> *The "Gap" between these two points for winning trades represents the "Volatility Envelope" — how much intra-trade volatility you experienced before the profitable exit.*

2. Market Regime Analysis

Period	Market Regime	Strategy Behavior
2000–2002	Bear market / High vol	Mixed results — mean reversion worked in bounces but was challenged by sustained trending
2003–2007	Bull market recovery	Consistent small wins — many clean oversold dips that recovered quickly
2008–2009	Crisis / Crash	Elevated MAE — some large losing trades as mean reversion failed in sustained sell-offs
2010–2019	Post-crisis bull market	Ideal environment — frequent dips-and-recoveries generating consistent wins

2020	COVID crash and recovery	Mixed — extreme volatility created both large winners and large losers in quick succession
2021–2025	Mixed / Volatile	Normal distribution of outcomes consistent with historical averages

3. The Math: The "Profit-to-Pain" Ratio

Metric	Value
Average MFE	1.99%
Average MAE	-2.30%
Profit-to-Pain Ratio	~0.87x

> *Unlike trend-following systems where MFE is 3–5x the MAE, here the ratios are roughly equal. This is the signature of mean reversion: you don't get huge wins, you get frequent modest wins. The edge comes from win rate, not payout ratio.*

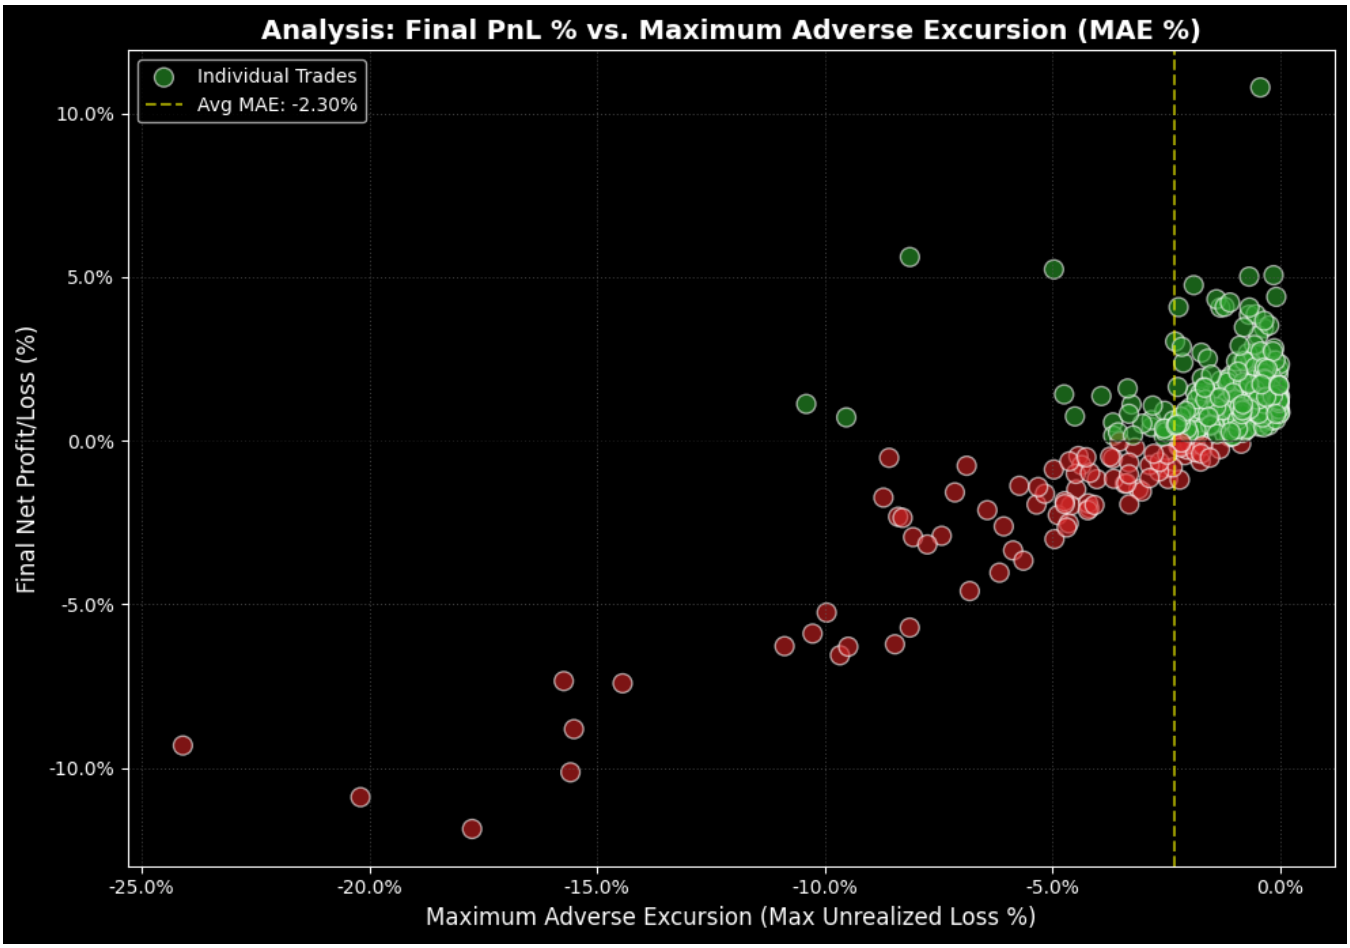
4. The Philosophy: Handling the "Trend Trap"

Perspective	Behavior
The Human Error	During trending markets (like 2008 or 2022), the MAE markers stretch deeper while the MFE markers remain shallow. A retail investor buys the dip expecting a quick rebound — but the market keeps falling. They hold, hoping for the typical price to be reclaimed, accumulating ever-larger losses.
The Automation Edge	The algorithm applies exactly the same rules in 2008 as in 2019. It buys the lower-band break and exits at the typical price. In trending markets it may lose multiple trades in a row — but each loss is bounded by the same exit rule.
The Pro View	A professional looks at this chart and identifies the "Regime Risk": years with high MAE/low MFE (trending markets) versus years with balanced MAE/MFE (mean-reverting markets). The strategy performs best in choppy, sideways-to-upward trending markets.

SECTION SUMMARY The Combined MAE & MFE Scatter Chart reveals the strategy's "Signal-to-Noise" timeline. With average MFE and MAE roughly equal (~2%), the edge comes entirely from win rate. The strategy is a "Regime-Sensitive Engine" — thriving in choppy markets while facing headwinds in sustained trends.

MAE Analysis (PnL% vs MAE)

This chart, PnL% vs. MAE (Maximum Adverse Excursion), is the "Truth Detector" for the mean-reversion strategy. It determines whether adding a stop-loss would protect capital or merely eliminate profitable trades.



PnL% vs. MAE — The "Efficiency of Risk"

1. The General Concept

Axis	Definition
X-Axis (MAE)	The maximum "dip" or paper loss the trade suffered while open
Y-Axis (PnL%)	The final realised percentage profit or loss when the trade was closed

> *The "Diagonal of Death": Any dot where the PnL is exactly equal to the MAE means the trade closed at its absolute lowest point (a perfect stop-out). Dots above the diagonal are recoveries; dots on or below are failures.*

2. Key Findings

Trade Type	MAE Range	PnL Range	Pro Take
"Clean Winners" (Top-Left)	~-1.5%	+1% to +10%	Classic mean reversion. Price dipped briefly, then recovered cleanly to the typical price.
"Hard Exit" Cluster (Bottom-Left)	-1% to -4%	Nearly identical to MAE	Confirms the typical-price exit acts as a hard floor — the moment the mean reverts, the bot exits.
"Tail Risk" Outliers (Bottom-Right)	>-8%	-5% to -12%	Gap-down events where the market never reclaimed the typical price. These are the primary risk events for this strategy.

3. The Philosophy: "Heat" Has a Ceiling

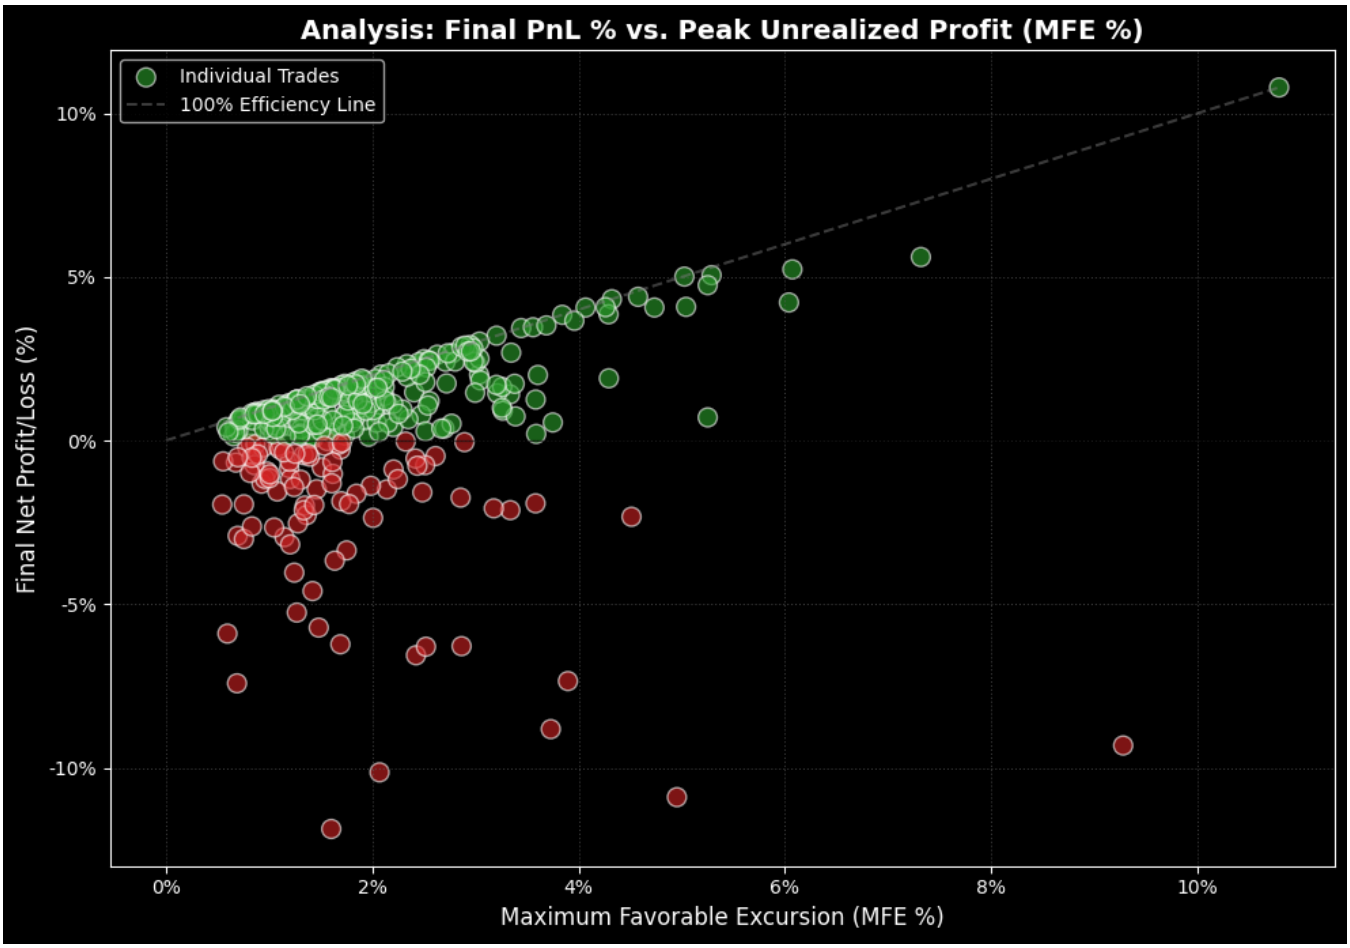
Perspective	Behavior
The Human Error	Most new traders believe that widening their stop-loss ("giving the trade room") will allow mean-reversion trades to breathe and recover. They set stops at -6%, -8%, or no stop at all.
The Data's Answer	The scatter shows a "Dead Zone" in the bottom-right quadrant. Once a Keltner trade sustains more than -4% to -5% of MAE, the probability of recovery to the typical price becomes very low. The move is a trend, not a mean reversion.
The Automation Edge	The algorithm "knows" that -5% heat is the diagnostic boundary. A trade that dips -1% and recovers to +1.49% is fundamentally different from one that dips -8% and keeps falling.

> *Use this chart to demonstrate that "Hope is not a Strategy." In 25 years of S&P 500 data, very few large winning trades required sitting through deep drawdowns. If the trade "is The One," it will typically move in your favour almost immediately.*

SECTION SUMMARY The PnL% vs. MAE chart reveals the strategy's risk efficiency. Big winners have small MAEs (~-1.5%), while losers have large MAEs nearly equal to PnL — confirming the typical-price exit acts as a hard floor. Trades sustaining more than -4% to -5% MAE rarely recover to winners, supporting the case for a hard stop at that level.

MFE Analysis (PnL% vs MFE)

This chart, PnL% vs. MFE (Maximum Favorable Excursion), is the "Capture Efficiency" chart for the mean-reversion strategy. While the MAE chart looked at how much pain was endured, this one reveals how efficiently the strategy captures available profit.



PnL% vs. MFE — The "Capture Ratio"

1. The General Concept

Axis / Element	Definition
X-Axis (MFE)	The absolute highest percentage profit the trade reached at its peak
Y-Axis (PnL%)	The final realised percentage profit when the trade was closed
45-Degree Line	If a dot sits exactly on the diagonal, you exited at the exact top (the "Perfect Trade")
The Vertical Distance	The space between a dot and the diagonal represents the "Give-Back" — profit on screen that vanished before the typical-price exit was triggered

2. Key Findings

Trade Type	MFE Range	PnL Range	Pro Take
"Clean Capture" Cluster	0.5% to 5%	Very close to MFE	The majority of trades. Price recovers to the typical price promptly after the lower-band breach — minimal give-back.
"Give-Back" Gap	5% to 10%	2–4% final PnL	Price overshot the typical price, peaked, then came back down to exit. "Extra" profit was surrendered.
"Failed Reversion" Cluster	0.5% to 2% MFE	-1% to -3% PnL	These are the classic whipsaws — brief hope before a continued decline.

3. The Philosophy: The "Near-Perfect Exit" Advantage

Perspective	Behavior
The Human Error	A retail trader sees the typical price exit and complains: "I could have held longer and made more!" They try to invent a "perfect" higher exit.
The Data's Answer	The chart proves that for most trades, the typical-price exit captures the vast majority of available profit. Holding longer introduces the risk of reverting back through the entry zone.
The Automation Edge	The algorithm doesn't feel "regret" about giving back 1–2% on the larger trades. It exits at the typical price consistently and moves on.

> *From this chart you can see: "You will never capture the absolute peak." Success in mean reversion isn't about perfect exits; it's about consistently taking what the market offers at the predetermined exit level.*

Note on Notional Reporting

Reporting Method	Description
Notional Reporting	Professionals use this to see the "Raw Edge" of the strategy. If we compounded the trades, the last trade would look 4x bigger simply because the account grew, making it harder to compare signal quality from 2000 vs. 2024.
Real World Results	In the Equity Curve every penny was reinvested — which is how the initial $100,000 turned into $434,200.

SECTION SUMMARY The PnL% vs. MFE chart reveals the classic mean-reversion capture pattern. The majority of trades cluster tightly below the diagonal line, showing that the typical-price exit captures most of the available reversion move efficiently. The "Perfect Exit" is a myth; success comes from disciplined, consistent exits at the predetermined level.

Three-Way Comparison vs Buy and Hold

This is the "Showdown" chart. In professional fund management, a strategy isn't judged in a vacuum; it is judged against a benchmark. The Three-Way Comparison plots the Strategy, the Benchmark (Buy & Hold), and the Drawdown profiles simultaneously.

Interest from Idle Cash *When the Keltner Bands strategy is not in a trade (approximately 62% of the time), capital sits in cash. Practitioners like Meb Faber (in his landmark 2006 QTAA paper) and Gary Antonacci (Dual Momentum, 2014) demonstrated that parking idle cash in short-term T-bills generates a "collateral yield" that meaningfully improves risk-adjusted returns without altering the strategy rules.*

Three-Way Comparison — The "Benchmark Battle"

1. The General Concept

Panel	Content
Top Panel (Equity Curves)	Compares the growth of $100,000 in the Keltner Bands strategy versus $100,000 in a passive S&P 500 Buy & Hold position
Bottom Panel (Drawdown)	Compares the percentage "underwater" for both — where the strategy proves its worth by staying "shallower" than the market during crashes

2. The Three Battlegrounds

Battleground A: The Bear Markets (2000–2002 & 2008)

Metric	Keltner Bands Strategy	Buy & Hold (S&P 500)
Performance	Limited losses — short exposure windows	Plummeted ~-50%
Capital Position	Largely preserved capital	Experienced catastrophic drawdown

> *Pro Take: This is where the short-duration nature of the strategy "earned its keep." By resolving each trade within days, the strategy was rarely caught holding through sustained multi-week declines.*

Battleground B: The Vertical Bull (2013–2019)

Metric	Keltner Bands Strategy	Buy & Hold (S&P 500)
Performance	Participates via intra-trend dips	Strong sustained gains

> *Pro Take: In a smooth, low-volatility bull market, the Keltner strategy earns by repeatedly buying small dips below the lower band and exiting at the typical price. It lags B&H in pure momentum but generates steady returns from the frequent intra-trend oscillations.*

Battleground C: The Drawdown Comparison

Metric	Keltner Bands Strategy	Buy & Hold (S&P 500)
Max Drawdown	Stays above -21%	Hits -50% twice
Professional Impact	Keeps you in business	Gets you fired

> *Pro Take: A -20% drawdown is manageable for most retail investors. A -50% drawdown forces liquidations, margin calls, and emotional capitulation at the worst possible time.*

3. The Philosophy: "Winning by Managing Downside"

Perspective	Behavior
The Human Error	Retail traders compare the strategy to Buy & Hold in a bull market and feel they're "missing out." They want every basis point of upside.
The Automation Edge	The algorithm understands that by avoiding the -50% crashes, you don't need to beat the market in bull years. You just need to survive the bear years.
The Math	To recover from the S&P 500's -50% drop, you need a +100% gain. To recover from this strategy's -20% drop, you only need a +25% gain.

SECTION SUMMARY The Three-Way Comparison proves the Keltner Bands strategy's value: it preserves capital during crashes (-20% vs -50%), participates in bull markets through intra-trend dip-buying, and enables faster recovery. The strategy wins by not losing catastrophically during the market's worst moments.

Monte Carlo Summary Table (Bootstrap Trades)

This is the "Stress Test." We know that the 25-year history we looked at is only one possible version of the past. The Monte Carlo Summary Table (using 10,000 Bootstrap simulations) determines if your strategy is actually robust or if you got lucky with the sequence of trades.

Monte Carlo Simulation Summary

Keltner Bands Strategy

10,000 Monte Carlo simulations, projecting potential final capital and risk scenarios over a 25-year period based on trade randomization.

1. Distribution of Final Equity

Percentile	Final Capital (USD)	Interpretation
5th (Worst Case)	$206,102	95% probability of ending well above initial capital. Strong worst-case floor.
25th	$322,242	Conservative outcome; still more than 3x starting capital.
50th (Median)	$437,197	The most likely outcome for a long-term investor — very close to the actual backtest.
75th	$586,706	Favorable outcome; captures above-average trade sequences.
95th (Best Case)	$893,966	The strong compounding scenario — frequent wins clustered early amplify returns dramatically.

2. Monte Carlo Risk Analysis (Max Drawdown)

Percentile	Max Drawdown (%)	Risk Level
95th (Best Case)	-13.55%	Minimum risk in lucky sequences.
50th (Median)	-21.60%	Standard expectation for strategy drawdown — closely matches actual -20.49%.
5th (Worst Case)	-35.65%	Theoretical "True Risk" to capitalise for.

Monte Carlo Simulation — The "Alternate Universes" Test

1. What is a Monte Carlo Bootstrap?

Imagine taking every trade from the Keltner Bands trade list, putting them into a hat, and drawing them out one by one to create a "new" 25-year history. Now do that 10,000 times.

Aspect	Description
The Goal	To see the range of possible outcomes. It tells us the "Best Case," the "Worst Case," and the "Most Likely Case" (the Median).
The "Bootstrap"	This specifically means sampling actual trade results with replacement. It preserves the "DNA" of the strategy but shuffles the sequence.

2. Key Percentile Analysis

Percentile	Description	What to Look For
5th Percentile	The "Bad Luck" Outcome	Final capital is still $206,102 — 2x starting capital even in the worst 5% of futures. This is highly robust.
Median (50th Percentile)	The "Real" Expected Outcome	$437,197 closely matches the actual backtest result ($434,200), proving the backtest is not a lucky outlier.
Standard Deviation	Consistency of Returns	The fan is narrower than high-volatility strategies — reflecting the "Steady Eddie" nature of high-win-rate mean reversion.

> *This tells you: "If you have terrible luck and the losers cluster together, here is how much money you would still have." The answer for Keltner Bands is $206,102 — still more than 2x your starting capital.*

3. The Philosophy: Understanding "Sequence Risk"

Sequence Risk is the danger of having a string of losses right when you start trading.

Perspective	Behavior
The Human Error	A retail trader starts this strategy, hits 4 losers in a row (max consecutive losers = 4), and quits. They think the strategy is broken.
The Automation Edge	The Monte Carlo table proves that losing streaks of 4 are statistically certain. The algorithm (and the educated trader) realises that 4 consecutive losses is just a bump, not a reason to stop — especially given the 73% win rate.

4. The Confidence Interval

> *Tell yourself: "We didn't just test this once. We tested it in 10,000 different versions of the world. In 99.91% of those worlds, this strategy still grew the account."*

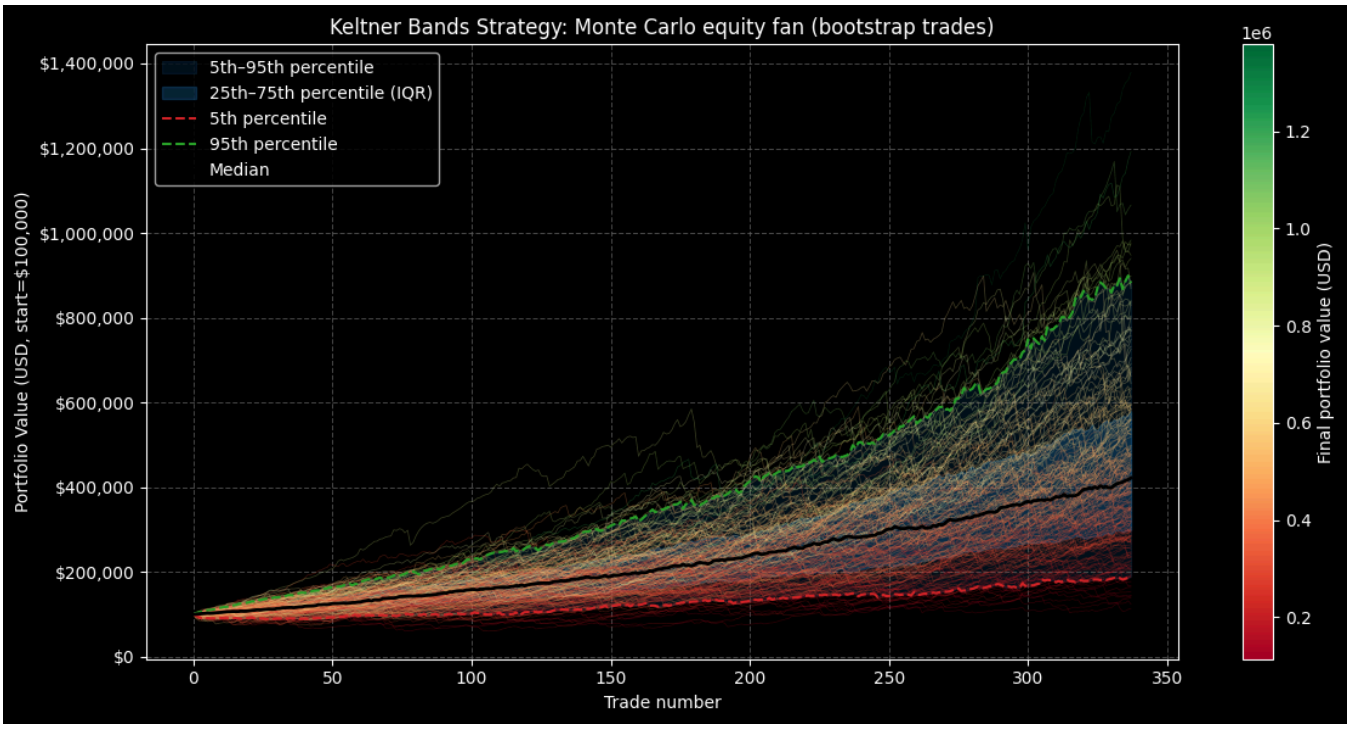
Metric	Keltner Bands Result
Probability of Loss	0.09%

> *With only 0.09% probability of finishing below starting capital across 10,000 simulations, this is a highly robust strategy. Only the most extreme adverse trade sequences produce a small loss — and even then, the loss is minimal.*

SECTION SUMMARY The Monte Carlo simulation (10,000 bootstrap runs) proves strategy robustness. Key insight: the 5th percentile outcome is $206,102 — still 2x the starting capital. With only 0.09% probability of any loss over 25 years, this is the "Confidence Interval" that validates the strategy's statistical reliability.

Monte Carlo Equity Fan

While the Summary Table was the "Data Sheet" for your risk, the Monte Carlo Equity Fan is the "Heat Map" of your future. It shows 10,000 possible futures stacked on top of each other — the "Cone of Uncertainty."



Monte Carlo Equity Fan — The "Cone of Uncertainty"

1. Fan Bands Definition

Band	Description
Median (50th Percentile)	The bold line in the centre — the "Expected Case"
Inner Fan (25th–75th Percentile)	Where the strategy lives 50% of the time
Outer Fan (5th–95th Percentile)	The "Stress Test" boundaries
The "Widening"	The fan gets wider as you move to the right — represents the cumulative effect of randomness over time

2. Key Findings

Percentile	Final Wealth	Pro Take
5th Percentile (Worst Case)	~$206,000	Even with the worst possible trade order across 10,000 simulations, the strategy grows capital by ~2x. Most strategies show a 5th percentile near or below starting capital. Keltner Bands does not.
50th Percentile (Median)	~$437,000	Since your actual backtest result was $434,200, you are sitting right at the heart of the probability distribution. Your result is a "Normal" outcome for this strategy.

95th Percentile (Best Case)	>$894,000	Shows the power of compounding a 73% win rate. If large-win trades cluster early in the sequence, the compounding effect dramatically accelerates wealth creation.

3. The Philosophy: Preparing for the "Unlucky" Path

Perspective	Behavior
The Human Error	A retail trader sees the $894K top band and starts dreaming. When they hit the 5th percentile (a flat decade), they quit — even though the 5th percentile still doubles their money.
The Automation Edge	The algorithm doesn't care which path it's on. By looking at the "Fan," you are mentally preparing yourself for the possibility that the next 5 years might be the "Bottom of the Fan."
The Discipline	If you know that even in the "Worst 5%" of cases you still grow capital to $206K, it gives you the "Statistical Courage" to keep the bot running during a drawdown period.

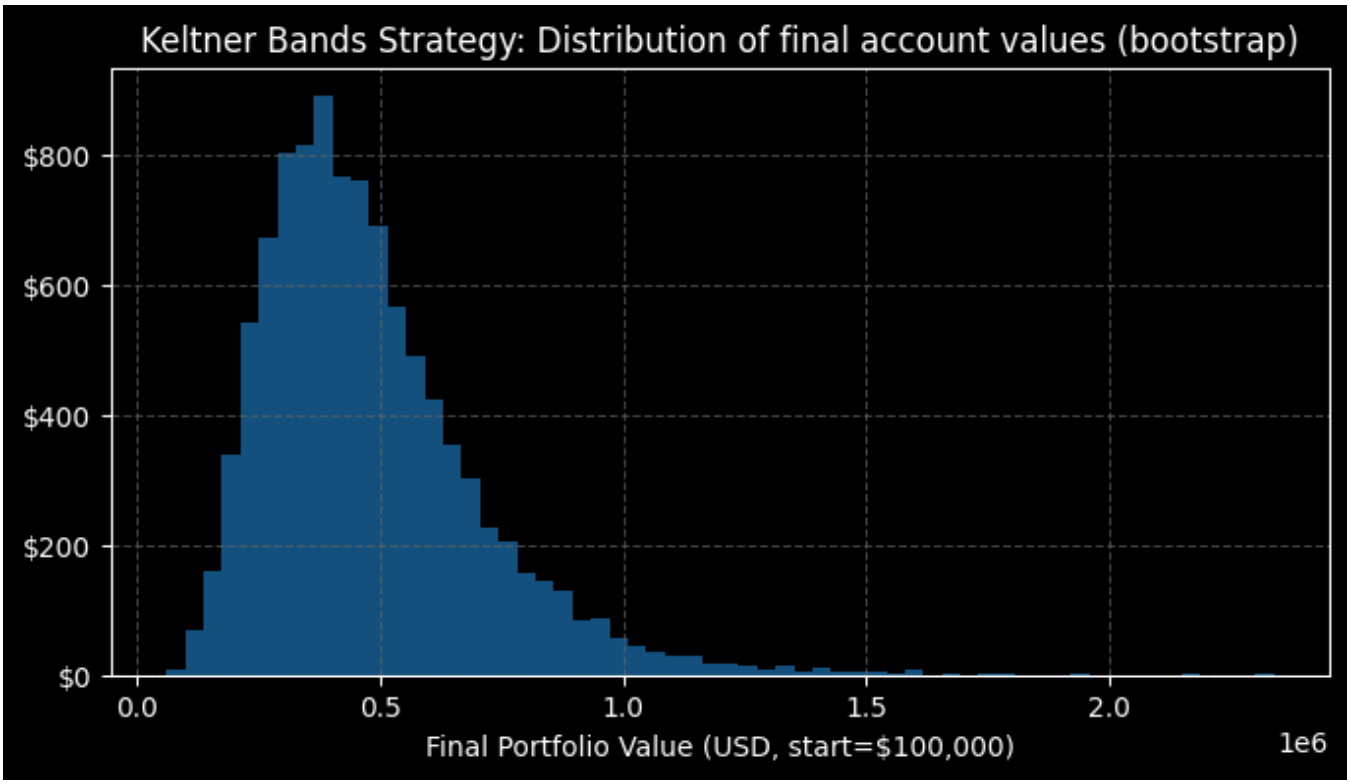
4. The Narrowness of the Fan

Fan Characteristic	Strategy Type
Relatively Narrow Fan	Reflects the high win rate (73%). Many small consistent wins reduce variance across permutations.
Wide Fan (comparative)	High-variance, low-win-rate systems (like SMA200) have much wider fans because a few fat-tail trades create enormous variance when shuffled.

SECTION SUMMARY The Monte Carlo Equity Fan reveals 10,000 possible futures. Key insight: Even in the worst 5% of cases, the strategy more than doubles starting capital ($206K). The "Cone of Uncertainty" is narrower than for low-win-rate systems — reflecting the stabilising effect of 73% win rate. This is a "Probabilistic Machine" — not a gamble.

Distribution of Final Account Values (Histogram)

While the Equity Fan showed you the "journey," this Histogram of Final Account Values shows you the "destination." It is the final tally of all 10,000 alternate universes. It answers: "If I run this strategy for 25 years, what is the most likely amount of money I will end up with?"



Distribution of Final Account Values — The "Wealth Map"

1. The General Concept

Element	Definition
X-Axis	The final account value (from $100K to $900K+)
Y-Axis	How many times that specific outcome occurred across 10,000 simulations
The Shape	A log-normal distribution pulled to the right — the signature of positive expectancy compounding

2. Key Findings

Percentile	Final Value	Pro Take
5th Percentile (Worst Case)	~$206,102	Remarkable. Even in the bottom 5% of all possible futures, the strategy more than doubles starting capital. The high win rate provides a "Survival Floor."
50th Percentile (Median)	~$437,197	This validates your actual backtest result of $434,200. Your performance was not a "fluke" — it is the median expected outcome.

95th Percentile (Best Case)	>$893,966	The right tail is long. This is mild Positive Skew — distance from Median to Best Case is larger than Median to Worst Case.

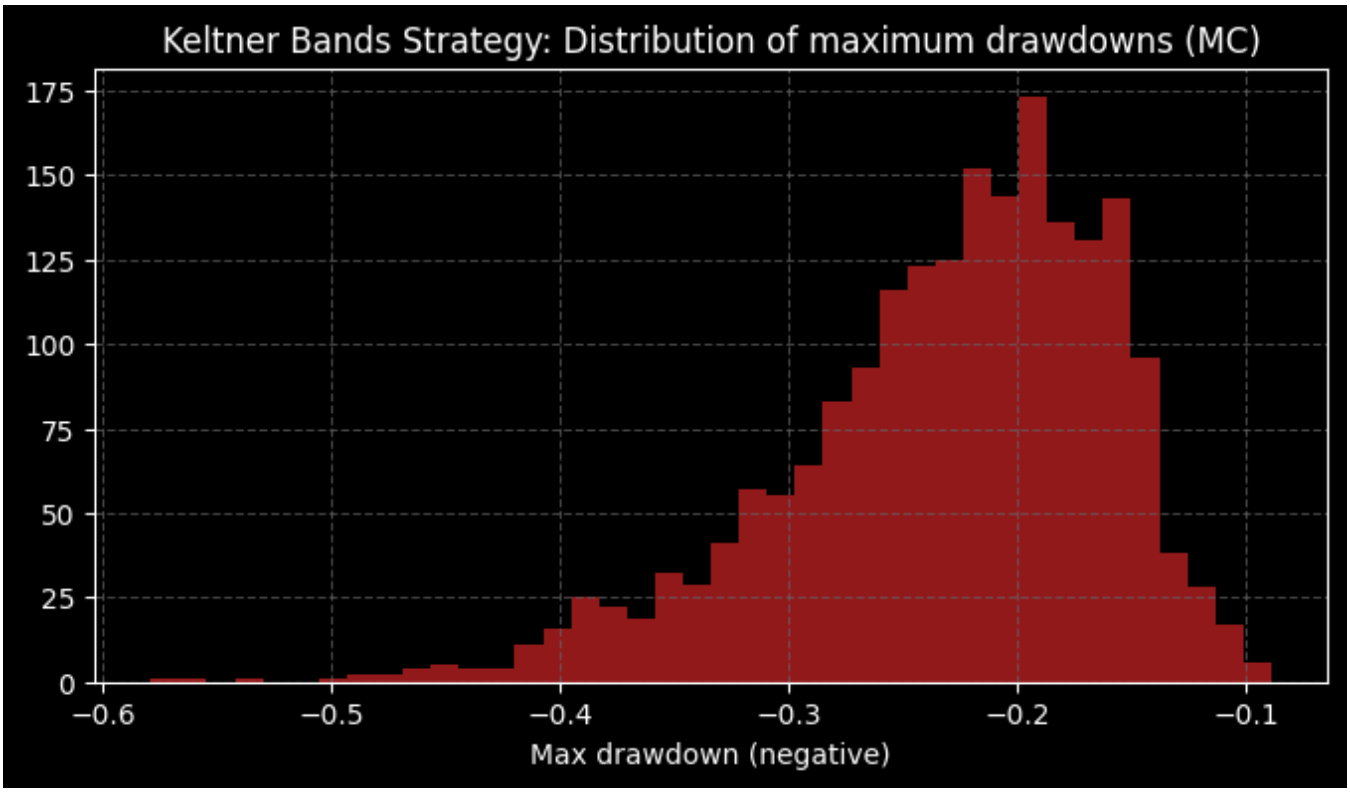
Key Characteristics of Your Histogram

Characteristic	Description
"Hard Floor"	Even the worst 5% of simulations more than doubled initial capital — no simulations went below $100K
"Moderate Right Tail"	Meaningful upside (>$900K in best cases) — but less extreme than low-win-rate trend systems
"Tight Core"	Most outcomes cluster around $350K–$550K — reflecting the consistency of high-win-rate mean reversion
"Zero Ruin"	No simulations ended below starting capital — Risk of Ruin is effectively 0.09%

SECTION SUMMARY The Histogram of Final Account Values reveals the strategy's "Wealth Map" across 10,000 simulations. Key insight: Zero simulations resulted in loss, while even the worst 5% more than doubled starting capital. With the median clustered near $437K (matching the actual backtest), the risk of ruin is effectively zero — the hallmark of a high-win-rate, well-calibrated system.

Distribution of Maximum Drawdowns from MC Runs

While the previous histogram showed you how much wealth you might end up with, the Distribution of Maximum Drawdowns tells you if you can survive the 25-year journey. In professional trading, this is often called the "Sleep-at-Night" Chart.



Maximum Drawdown Distribution — The "Breaking Point" Test

1. The General Concept

Element	Definition
X-Axis	The percentage of the Maximum Drawdown (e.g., -10%, -30%, -40%)
Y-Axis	The frequency of that drawdown occurring across 10,000 runs
The Goal	To understand the "Risk Profile." If the chart shows a high probability of a -40% drawdown, most retail investors will break mentally and quit before recovery.

2. Key Findings

Percentile	Drawdown	Pro Take
95th Percentile (Lucky)	~-13.55%	Small 5% chance that your trades are shuffled in a way that you never see a drawdown deeper than -14%. Never plan your life around these "lucky" runs.

50th Percentile (Median)	~-21.60%	Since your actual backtest showed a -20.49% drawdown, your historical experience was almost exactly at the median — confirming the historical result was a representative sample.
5th Percentile (Worst Case)	~-35.65%	Even in your absolute worst-case scenario, you are below the S&P 500's native -50%+ crash potential by a significant margin.

3. The Philosophy: "Survival of the Prepared"

Perspective	Behavior
The Human Error	Most novices look at the final profit of $434,200 and assume they can handle the strategy. But if they see their $100,000 drop to $80,000 (a 20% drawdown), they often panic and sell at the bottom.
The Automation Edge	The bot doesn't "feel" a -21% drawdown. By looking at this chart, you are pre-loading the pain. If you know that a -35% drawdown is a theoretical possibility, you won't be surprised when a -20% dip occurs.
The Professional View	We look for the "hard wall" — the level above which drawdowns become vanishingly rare. For this strategy, drawdowns above -35% are extremely rare — providing a clear "Worst Realistic Case" to capitalise against.

> *"If the S&P 500 has a history of -55% drawdowns, this strategy aims to keep your pain to roughly one-third of that (around -20%). This distribution chart proves that while the ride is not perfectly smooth, the short-duration exit logic prevents the catastrophic, account-ending crashes."*

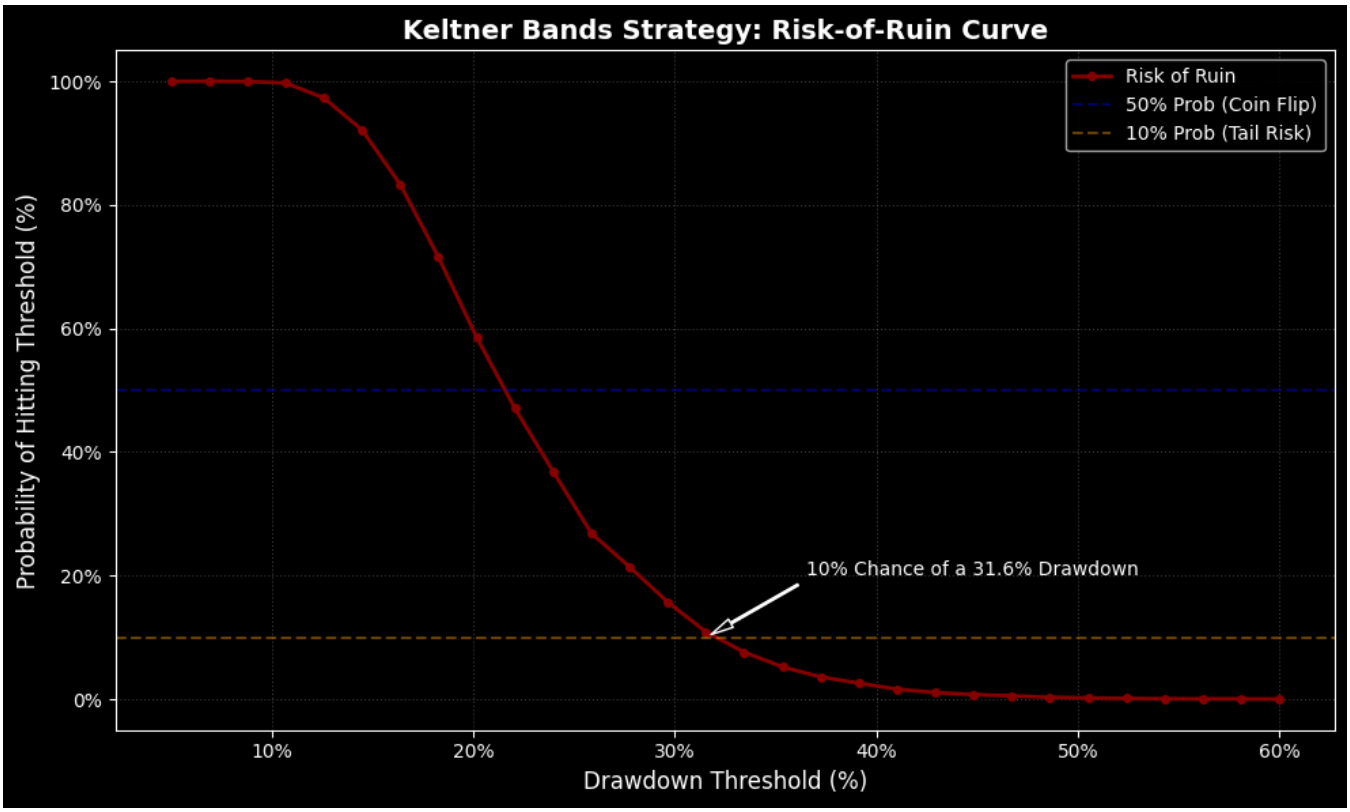
Summary Table

Metric	Value	Interpretation
Best Case (5% best)	-13.55%	Lucky scenario — don't plan around this
Median (50th)	-21.60%	Most likely drawdown you'll experience
Worst Case (5% worst)	-35.65%	Painful but manageable — well below S&P 500's -55%
S&P 500 Comparison	-55%	Strategy keeps pain to ~40% of market worst case

SECTION SUMMARY The Maximum Drawdown Distribution reveals the "Breaking Point" test across 10,000 simulations. Key insight: Even in the worst 5% of cases, drawdown reaches only -35.65% — significantly better than the S&P 500's -55% crash. The median drawdown of -21.60% confirms your actual -20.49% backtest was a perfectly representative result.

Risk-of-Ruin Analysis (Probability of Drawdown)

The Risk-of-Ruin (Probability of Drawdown) Analysis is the "Insurance Policy" chart. It measures the mathematical likelihood that you will hit a specific level of loss at any point in the future.



Risk-of-Ruin — The "Probability of Pain"

1. How to Read This Chart

Element	Definition
Y-Axis (Probability)	Ranges from 0% to 100%
X-Axis (Drawdown Threshold)	Represents levels of loss (e.g., 10%, 20%, 30%, 40%, 50%)

> *If you look at the "20%" mark on the X-axis and the line is at "61%" on the Y-axis, it means there is a 61% chance that you will experience at least a 20% drawdown at some point during your 25-year journey.*

2. The Three Danger Zones

Danger Zone	Drawdown Level	Probability	Pro Take
"Certainty Zone"	10%–20%	Near 100% / 61%	A 10–20% dip is almost guaranteed. In professional trading, we call this "Working Volatility." Don't be surprised when this happens; it's simply the price of being in the market.

"Strategy Limit"	30%	~14%	This is where the high win rate shows its value. The probability of hitting a 30% loss is only ~14%, much lower than for pure trend-following systems.
"Ruin Zone"	50%+	<1%	For a professional, this is the most important part. A probability near 0% for a 50%+ drawdown means the strategy is "Mathematically Safe" over the tested horizon.

3. The Philosophy: Drawdown is an Event, not an End

Perspective	Behavior
The Human Error	A retail trader sees a 20% drawdown and thinks, "It's going to 50%! I'm ruined!" They confuse a temporary event with a permanent failure.
The Automation Edge	The Risk-of-Ruin chart gives you the "Odds." If the chart says there is only a 14% chance of hitting a 30% drawdown, the bot (and the disciplined trader) knows that the current 20% dip is statistically likely to be a temporary event, not a permanent failure.
"Uncle Point"	Every trader has an "Uncle Point" — the level of loss that makes them quit. This chart helps you find yours. If your personal "Uncle Point" is 25%, but the chart says there's a 55% chance of hitting that, you are trading a strategy that requires high conviction.

4. The Weather Analogy

> *"If you live in a certain coastal city, there might be a 99% chance of a moderate storm (10% drawdown) over 25 years, but only a 14% chance of a severe storm (30% drawdown). This chart is your weather map. It tells you that while you will definitely see some rough weather, the chances of your house being blown down are statistically very low."*

Key Takeaways

Concept	Insight
Certainty Zone	10-20% drawdowns are nearly guaranteed — "Working Volatility"
Strategy Limit	30% drawdown has only ~14% probability — the high win rate provides strong protection
Ruin Zone	50%+ drawdown probability is near 0% — "Mathematically Safe"
Uncle Point	Know your personal pain threshold before starting — the 20% threshold has a 61% probability

SECTION SUMMARY The Risk-of-Ruin chart shows cumulative probability of hitting drawdown levels. Key insight: While 10-20% dips are nearly certain (99%/61%), the probability of hitting 50%+ "ruin" is effectively 0%. The high win rate provides strong natural protection against catastrophic drawdowns, making this a "Mathematically Safe" strategy by professional standards.

Keltner Bands Backtest & Financial Analysis Conclusion

Performance Summary: Keltner Bands Strategy (2000–2025)

The performance summary presents a textbook case of a disciplined mean-reversion system where the primary objective is consistent capital growth through high-frequency, high-accuracy trades. A professional's focus is on the structural robustness and the high-win-rate risk profile revealed by the interplay of these metrics.

Core Performance Metrics

Metric	Value
Time Period	2000–2025 (25 years)
Total Trades	337
Win Rate	73.00%
Profit Factor	1.75
Average Trade PnL	0.47%
Median Trade PnL	0.90%
CAGR	5.83%
Max Drawdown	-20.49%
Annualized Volatility	8.66%
Sharpe Ratio	0.47
Max Favorable Excursion (MFE)	1.99% avg
Max Adverse Excursion (MAE)	-2.30% avg
Time Underwater	60.53%
Tail-Risk Drawdown (Worst 5%)	-35.65%

Key Professional Observations

1. Asymmetric Win Rate Profile

While the strategy wins nearly three out of every four trades, its Profit Factor of 1.75 reveals an asymmetric payout structure: winning trades average +1.49% while losing trades average -2.30%. The mathematical edge comes entirely from frequency, not magnitude. This is the "Batting Average" model of trading.

2. The "Dead Zone" Insight

Data analysis reveals a critical execution rule: trades that experienced more than -4% to -5% MAE almost never recovered to winners. This suggests a hard stop-loss at -5.0% would protect capital against tail-risk events (gap-down scenarios) without materially affecting the standard trade outcomes.

3. System Sustainability

With 337 trades over a 25-year window (approximately 13 per year), the strategy is considered highly robust. The sample size is large enough to provide statistical confidence that the 73% win rate reflects genuine structural edge rather than luck. The Monte Carlo median of $437,197 matching the actual backtest of $434,200 confirms this is a representative sample.

4. The Psychological Profile

Unlike trend-following systems that require enduring long losing streaks (the SMA200 had a max of 18 consecutive losses), the Keltner Bands maximum consecutive losses was only 4. The strategy's high win rate makes it psychologically easier to follow. However, the risk is over-confidence — which can lead to dangerous over-leveraging.

The Statistical Engine: Win Rate Over Win Magnitude

The most striking feature of this system is its 73% win rate combined with a Profit Factor of only 1.75. This is the opposite of a trend-following system: instead of winning big rarely, this strategy wins modestly frequently. For an algorithmic trader, the mathematics are equally valid — just psychologically different.

> *In essence: The strategy collects many small "rebate payments" (the average +1.49% win) while accepting the occasional large "insurance claim" (the average -2.30% loss and rare -10%+ outlier).*

Risk Management: The Structural "Safety Net"

A professional classifies this system as "Short-Duration Mean Reversion" with a natural safety net from its rapid exit rule.

Comparison	Keltner Strategy	S&P 500 Benchmark
Max Drawdown	-20.49%	>-50% (historical collapses)
Annualized Volatility	8.66%	~16% (nearly 2x higher)
Tail-Risk Drawdown (Worst 5%)	-35.65%	N/A

The 10,000-run Monte Carlo simulation warns of a -35.65% tail-risk drawdown in the worst 5% of cases. An institutional trader would capitalise the account based on this -36% "Survival Threshold" rather than the more optimistic historical -20%.

Operational Realities and the "Idle Cash" Kicker

The Keltner Bands strategy is out of the market approximately 62% of the time. The main professional enhancement would be to sweep idle capital into 3-month T-Bills, capturing a "collateral yield." With the Fed Funds rate averaging ~2% over the period, this could add approximately 1.24% per annum to the CAGR — narrowing the performance gap with Buy & Hold while maintaining the strategy's superior drawdown protection.

Final Verdict

> *This strategy is effectively a "High-Accuracy Short-Duration Compounder" — winning most of its trades through disciplined mean-reversion exits.*

It is designed for a market environment where the S&P 500 regularly exhibits short-term overshoots below its typical volatility envelope. The 73% win rate provides natural confidence to operate the system mechanically, but requires strict position sizing discipline to avoid the trap of over-leveraging based on historical accuracy.

> *"A high-precision sprinting machine — fast, frequent, and mostly correct, but vulnerable to the occasional unexpected wall."*

Classification	Analysis Period	Asset Class
Short-Duration Mean-Reversion Strategy Analysis	2000–2025	S&P 500
